STATA PROGRAMMING REFERENCE
MANUAL
RELEASE 15

A Stata Press Publication
StataCorp LLC
College Station, Texas
makemcs ................................................................. Constrained estimation 311
mark .......................................................... Mark observations for inclusion 317
markdown .......................................................... Convert Markdown document to an HTML file 324
matlist .................................................. Display a matrix and control its format 326
matrix .......................................................... Introduction to matrix commands 338
matrix accum ................................................... Form cross-product matrices 342
matrix define ................................................ Matrix definition, operators, and functions 351
matrix dissimilarity .............................................. Compute similarity or dissimilarity measures 368
matrix eigenvvalues ............................................ Eigenvalues of nonsymmetric matrices 373
matrix get ................................................ Access system matrices 376
matrix mkmat .............................................. Convert variables to matrix and vice versa 379
matrix rrownames .............................................. Name rows and columns 385
matrix score ................................................ Score data from coefficient vectors 390
matrix svd .................................................. Singular value decomposition 393
matrix symeigen .............................................. Eigenvalues and eigenvectors of symmetric matrices 396
matrix utility ................................................ List, rename, and drop matrices 399
more .......................................................... Pause until key is pressed 402
nopreserve option ........................................... nopreserve option 403
numlist ........................................................ Parse numeric lists 404
pause ...................................................... Program debugging command 407
plugin ........................................................ Load a plugin 410
postfile .................................................. Post results in Stata dataset 411
._predict ................................................ Obtain predictions, residuals, etc., after estimation programming command 415
preserve .................................................. Preserve and restore data 417
program ............................................. Define and manipulate programs 420
program properties ........................................ Properties of user-defined programs 425
Project Manager ........................................... Organize Stata files 430
putdocx ................................................ Generate Office Open XML (.docx) file 436
putexcel ................................................ Export results to an Excel file 462
putexcel advanced ......................................... Export results to an Excel file using advanced syntax 482
putpdf ................................................ Create a PDF file 497
quietly .................................................. Quietly and noisily perform Stata command 521
._return ................................................ Preserve stored results 525
return .................................................. Return stored results 528
._rmcoll ................................................ Remove collinear variables 538
rmsg .................................................. Return messages 542
._robust ................................................ Robust variance estimates 543
scalar ........................................................ Scalar variables 567
serset .................................................. Create and manipulate sersets 574
set locale_functions ............................... Specify default locale for functions 583
set locale_ui ................................................ Specify a localization package for the user interface 584
signestimationsample ................................... Determine whether the estimation sample has changed 585
sleep .................................................. Pause for a specified time 588
smcl ................................................ Stata Markup and Control Language 589
sortpreserve ................................................ Sort within programs 613
syntax ................................................ Parse Stata syntax 617
sysdir ................................................ Query and set system directories 633
tabdisp ................................................ Display tables 638
Contents

timer ........................................ Time sections of code by recording and reporting time spent 649
_tokenize ................................................... Divide strings into tokens 651
trace .................................................... Debug Stata programs 653
unab ................................................................ Unabbreviate variable list 659
unabcmd ................................................ Unabbreviate command name 662
varabbrev ................................................. Control variable abbreviation 663
version ..................................................... Version control 664
viewsourcing ............................................. View source code 668
while ......................................................... Looping 669
window programming ............................... Programming menus and windows 672
window fopen ................................................. Display open/save dialog box 673
window manage ........................................... Manage window characteristics 675
window menu ............................................... Create menus 680
window push ............................................... Copy command into Review window 688
window stopbox .......................................... Display message box 689
Subject and author index .......................................................... 691
Combined subject table of contents

This is the complete contents for this manual. References to inserts from other Stata manuals that we feel would be of interest to programmers are also included.

Data manipulation and management

Functions and expressions

[U] Section 12.4.2.1 .......................................................... Unicode string functions
[U] Chapter 13 ................................................................. Functions and expressions
[FN] Date and time functions ...................................................
[FN] Mathematical functions ....................................................
[FN] Matrix functions ..........................................................
[FN] Programming functions ......................................................
[FN] Random-number functions ..................................................
[FN] Selecting time-span functions ............................................
[FN] Statistical functions .....................................................
[FN] String functions ..........................................................
[FN] Trigonometric functions ....................................................
[D] egen ................................................................. Extensions to generate

Strings

[U] Section 12.4 ................................................................. Strings
[U] Section 12.4.2 ............................................................. Handling Unicode strings
[U] Chapter 23 ................................................................. Working with strings
[FN] String functions ..........................................................
[D] data types ............................................................... Quick reference for data types
[D] unicode ................................................................. Unicode utilities
Dates and times

[U] Section 12.5.3 ........................................... Date and time formats
[U] Chapter 24 .................................................. Working with dates and times
[D] bcal ......................................................... Business calendar file manipulation
[D] datetime ................................................... Date and time values and variables
[D] datetime business calendars ................................ Business calendars
[D] datetime business calendars creation ....................... Business calendars creation
[D] datetime display formats .................................. Display formats for dates and times
[D] datetime translation ....................................... String to numeric date translation functions

Utilities

Basic utilities

[GS] Chapter 13 (GSM, GSU, GSW) ........... Using the Do-file Editor—automating Stata
[U] Chapter 4 ................................................... Stata’s help and search facilities
[U] Chapter 15 .................................................. Saving and printing output—log files
[U] Chapter 16 .................................................. Do-files
[R] about ................................................. Display information about your Stata
[D] by ...................................................... Repeat Stata command on subsets of the data
[R] cls ..................................................... Clear Results window
[R] copyright .............................................. Display copyright information
[R] do ...................................................... Execute commands from a file
[R] doedit .................................................. Edit do-files and other text files
[R] exit ..................................................... Exit Stata
[R] help .................................................... Display help in Stata
[R] level ................................................... Set default confidence level
[R] log ..................................................... Echo copy of session to file
[D] obs .................................................... Increase the number of observations in a dataset
[R] postest .................................................. Postestimation Selector
[R] #review .............................................. Review previous commands
[R] search ................................................ Search Stata documentation and other resources
[BAYES] set clevel ........................................ Set default credible level
[R] translate ................................................ Print and translate logs
[D] unicode translate ..................................... Translate files to Unicode
[R] view .................................................. View files and logs
[D] zipfile .............................................. Compress and uncompress files and directories in zip archive format

Error messages

[U] Chapter 8 .................................................. Error messages and return codes
[P] error ..................................................... Display generic error message and exit
[R] error messages ....................................... Error messages and return codes
[P] errmsg ................................................ Return messages

Stored results

[U] Section 13.5 ........................................... Accessing coefficients and standard errors
[U] Section 18.8 ........................................... Accessing results calculated by other programs
[U] Section 18.9 ........................................... Accessing results calculated by estimation commands
[U] Section 18.10 ........................................ Storing results
[P] creturn ................................................ Return c-class values
[P] ereturn ................................................ Post the estimation results
[R] estimates ............................................. Save and manipulate estimation results

### Advanced utilities

| D | assert | Verify truth of claim               |
| D | cd     | Change directory                    |
| D | changeeol | Convert end-of-line characters of text file |
| D | checksum | Calculate checksum of file         |
| D | copy   | Copy file from disk or URL          |
| P | _datassignature | Determine whether data have changed |
| D | datassignature | Determine whether data have changed |
| R | db     | Determine whether data have changed |
| P | dialog programming | Launch dialog |
Matrix commands

Basics

[U] Chapter 14 .................................................. Matrix expressions
[P] matlist .................................................. Display a matrix and control its format
[P] matrix .................................................. Introduction to matrix commands
[P] matrix define ........................................ Matrix definition, operators, and functions
[P] matrix utility .......................................... List, rename, and drop matrices

Programming

[P] ereturn .................................................. Post the estimation results
[P] matrix accum ......................................... Form cross-product matrices
[P] matrix rownames ..................................... Name rows and columns
[P] matrix score .......................................... Score data from coefficient vectors
[R] ml ...................................................... Maximum likelihood estimation

Other

[P] makecns ................................................. Constrained estimation
[P] matrix dissimilarity ............................... Compute similarity or dissimilarity measures
[P] matrix eigenvalues .................................. Eigenvalues of nonsymmetric matrices
[P] matrix get ............................................... Access system matrices
[P] matrix mkmat .......................................... Convert variables to matrix and vice versa
[P] matrix svd ............................................... Singular value decomposition
[P] matrix symeigen ................................. Eigenvectors of symmetric matrices

Mata

[D] putmata .............................................. Put Stata variables into Mata and vice versa

Programming

Basics

[U] Chapter 18 ............................................. Programming Stata
[U] Section 18.3 .............................................. Macros
[U] Section 18.11 .......................................... Ado-files
[P] comments ............................................... Add comments to programs
[P] fexpand .................................................. Expand factor varlists
[P] macro .................................................... Macro definition and manipulation
[P] program ............................................... Define and manipulate programs
[P] return .................................................... Return stored results

Program control

[U] Section 18.11.1 ...................................... Version
[P] capture .................................................. Capture return code
[P] continue ............................................... Break out of loops
[P] error .................................................... Display generic error message and exit
[P] foreach .................................................. Loop over items
[P] forvalues ............................................. Loop over consecutive values
[P] if .......................................................... if programming command
[P] version .................................................. Version control
[P] while ..................................................... Looping

Parsing and program arguments

[U] Section 18.4 ............................................. Program arguments
[P] confirm .................................................. Argument verification
[P] gettoken ............................................... Low-level parsing
[P] levelsof ............................................... Levels of variable
[P] numlist ................................................ Parse numeric lists
[P] syntax ................................................ Parse Stata syntax
[P] tokenize ............................................... Divide strings into tokens

Console output

[U] Section 12.4.2 ......................................... Handling Unicode strings
[P] dialog programming ................................... Dialog programming
[P] display ............................................... Display strings and values of scalar expressions
[P] smcl ..................................................... Stata Markup and Control Language
Commonly used programming commands

- byable
- #delimit
- exit
- fvrevar
- mark
- matrix
- more
- nopreserve option
- preserve
- quietly
- scalar
- smcl
- sortpreserve
- timer
- tsrevar
- tabdisp
- unicode

Debugging

- pause
- timer
- trace

Advanced programming commands

- Section 12.4.2.5
- Pdf*()
- _docx*()
- automation
- break
- char
- class
- class exit
- classutil
- dynamic tags
- dyndoc
- dyntext
- estat programming
- _estimates
- estimation command
- file
- findfile
- include
- java
- javacall
- macro
- macro lists
- markdown
- ml
M-5  moptimize( ) ................................. Model optimization
M-5  optimize( ) ................................. Function optimization
P    plugin ........................................ Load a plugin
P    postfile ....................................... Post results in Stata dataset
P    _predict  Obtain predictions, residuals, etc., after estimation programming command
P    program properties ......................... Properties of user-defined programs
P    putdocx ...................................... Generate Office Open XML (.docx) file
P    putexcel advanced .......................... Export results to an Excel file using advanced syntax
D    putmata ...................................... Put Stata variables into Mata and vice versa
P    putpdf ........................................ Create a PDF file
P    _return ...................................... Preserve stored results
P    _rmcoll ...................................... Remove collinear variables
P    _robust ...................................... Robust variance estimates
P    serset ....................................... Create and manipulate sersets
D    snapshot ..................................... Save and restore data snapshots
P    unab ......................................... Unabbreviate variable list
P    unabcmd ..................................... Unabbreviate command name
D    unicode collator ............................ Language-specific Unicode collators
D    unicode convertfile ....................... Low-level file conversion between encodings
P    varabbrev ................................... Control variable abbreviation
P    viewsource ................................... View source code
M-5  xl( ) .......................................... Excel file I/O class

Special-interest programming commands

[R]    bstat ........................................ Report bootstrap results
[MV]   cluster programming subroutines ........ Add cluster-analysis routines
[MV]   cluster programming utilities ........ Cluster-analysis programming utilities
[R]    fvarevar .................................. Factor-variables operator programming command
[P]    matrix dissimilarity ...................... Compute similarity or dissimilarity measures
[MI]   mi select .................................. Programmer’s alternative to mi extract
[ST]   st_is ....................................... Survival analysis subroutines for programmers
[SVY]  svymarkout  ................................ Mark observations for exclusion on the basis of survey characteristics
[MI]   technical .................................. Details for programmers
[TS]   tsrevar ................................... Time-series operator programming command

Projects

[P]    Project Manager ............................ Organize Stata files

File formats

[P]    file formats .dta .......................... Description of .dta file format
[D]    unicode convertfile ..................... Low-level file conversion between encodings
[D]    unicode translate ....................... Translate files to Unicode

Mata

Automated document and report creation

[P]    dynamic tags .............................. Dynamic tags for Markdown documents
[P]    dyndoc ..................................... Convert dynamic Markdown document to an HTML file
[P]    dyntext .................................... Process Stata dynamic tags in text file
markdown ............................. Convert Markdown document to an HTML file
putdocx .............................. Generate Office Open XML (.docx) file
putexcel ................................ Export results to an Excel file
putpdf .................................. Create a PDF file

Interface features

Chapter 1 (GSM, GSU, GSW) .............................. Introducing Stata—sample session
Chapter 2 (GSM, GSU, GSW) .............................. The Stata user interface
Chapter 3 (GSM, GSU, GSW) .............................. Using the Viewer
Chapter 6 (GSM, GSU, GSW) .............................. Using the Data Editor
Chapter 7 (GSM, GSU, GSW) .............................. Using the Variables Manager
Chapter 13 (GSM, GSU, GSW) .................. Using the Do-file Editor—automating Stata
Chapter 15 (GSM, GSU, GSW) .................. Editing graphs
dialog programming ................................. Dialog programming
dooedit .................................. Edit do-files and other text files
set locale_ui ................................. Specify a localization package for the user interface
sleep ........................................... Pause for a specified time
smcl ..................................... Stata Markup and Control Language
unicode locale ................................. Unicode locale utilities
varmanage ................................ Manages variable labels, formats, and other properties
viewsource .................................. View source code
window fopen ................................. Display open/save dialog box
window manage ................................ Manage window characteristics
window menu .................................... Create menus
window programming ............................ Programming menus and windows
window push ................................. Copy command into Review window
window stopbox ............................... Display message box
Cross-referencing the documentation

When reading this manual, you will find references to other Stata manuals. For example,

[U] 26 Overview of Stata estimation commands
[R] regress
[D] reshape

The first example is a reference to chapter 26, *Overview of Stata estimation commands*, in the *User’s Guide*; the second is a reference to the **regress** entry in the *Base Reference Manual*; and the third is a reference to the **reshape** entry in the *Data Management Reference Manual*.

All the manuals in the Stata Documentation have a shorthand notation:

- [GSM] Getting Started with Stata for Mac
- [GSU] Getting Started with Stata for Unix
- [GSW] Getting Started with Stata for Windows
- [U] Stata User’s Guide
- [R] Stata Base Reference Manual
- [BAYES] Stata Bayesian Analysis Reference Manual
- [D] Stata Data Management Reference Manual
- [FN] Stata Functions Reference Manual
- [XT] Stata Longitudinal-Data/Panel-Data Reference Manual
- [MI] Stata Multiple-Imputation Reference Manual
- [PSS] Stata Power and Sample-Size Reference Manual
- [SVY] Stata Survey Data Reference Manual
- [I] Stata Glossary and Index
In this manual, you will find

- matrix-manipulation commands, which are available from the Stata command line and for ado-programming (for advanced matrix functions and a complete matrix programming language, see the *Mata Reference Manual*)
- commands for programming Stata, and
- commands and discussions of interest to programmers.

This manual is referred to as [P] in cross-references and is organized alphabetically.

If you are new to Stata’s programming commands, we recommend that you first read the chapter about programming Stata in the *User’s Guide*; see [U] 18 Programming Stata. After you read that chapter, we recommend that you read the following sections from this manual:

- [P] program Define and manipulate programs
- [P] sortpreserve Sorting within programs
- [P] byable Making programs byable
- [P] macro Macro definition and manipulation

You may also find the subject table of contents helpful; it immediately follows the table of contents.

We also recommend the Stata NetCourses®. At the time this introduction was written, our current offerings of Stata programming NetCourses included

- NC-151 Introduction to Stata programming
- NC-152 Writing Your Own Stata Commands

You can learn more about NetCourses and view the current offerings of NetCourses by visiting http://www.stata.com/netcourse/.

- [R] intro — Introduction to base reference manual
Automation (formerly known as OLE Automation) is a communication mechanism between Microsoft Windows applications. It provides an infrastructure whereby Windows applications (automation clients) can access and manipulate functions and properties implemented in another application (automation server). A Stata Automation object exposes internal Stata methods and properties so that Windows programmers can write automation clients to directly use the services provided by Stata.

Remarks and examples

A Stata Automation object is most useful for situations that require the greatest flexibility to interact with Stata from user-written applications. A Stata Automation object enables users to directly access Stata macros, scalars, stored results, and dataset information in ways besides the usual log files.

For documentation on using a Stata Automation object, see http://www.stata.com/automation/.

Note that the standard Stata end-user license agreement (EULA) does not permit Stata to be used as an embedded engine in a production setting. If you wish to use Stata in such a manner, please contact StataCorp at service@stata.com.

Also see

[P] plugin — Load a plugin
Description

nobreak temporarily turns off recognition of the Break key. It is seldom used. break temporarily reestablishes recognition of the Break key within a nobreak block. It is even more seldom used.

Syntax

nobreak stata_command

break stata_command

Typical usage is

nobreak {
    ...  
    capture noisily break ...  
    ...  
}

Remarks and examples

Stata commands honor the Break key. This honoring is automatic and, for the most part, requires no special code, as long as you follow these guidelines:

1. Obtain names for new variables from tempvar; see [U] 18.7.1 Temporary variables.
2. Obtain names for other memory aggregates, such as scalars and matrices, from tempname; see [U] 18.7.2 Temporary scalars and matrices.
3. If you need to temporarily change the user’s data, use preserve to save it first; see [U] 18.6 Temporarily destroying the data in memory.
4. Obtain names for temporary files from tempfile; see [U] 18.7.3 Temporary files.

If you follow these guidelines, your program will be robust to the user pressing Break because Stata itself will be able to put things back as they were.

Still, sometimes a program must commit to executing a group of commands that, if Break were honored in the midst of the group, would leave the user’s data in an intermediate, undefined state. nobreak is for those instances.
Example 1

You are writing a program and following all the guidelines listed above. In particular, you are using temporary variables. At a point in your program, however, you wish to list the first five values of the temporary variable. You would like, temporarily, to give the variable a pretty name, so you temporarily rename it. If the user were to press Break during the period, the variable would be renamed; however, Stata would not know to drop it, and it would be left behind in the user’s data. You wish to avoid this. In the code fragment below, ‘myv’ is the temporary variable:

```stata
nobreak {
    rename ‘myv’ Result
    list Result in 1/5
    rename Result ‘myv’
}
```

It would not be appropriate to code the fragment as

```stata
nobreak rename ‘myv’ Result
nobreak list Result in 1/5
nobreak rename Result ‘myv’
```

because the user might press Break during the periods between the commands.

Also see

- [P] capture — Capture return code
- [P] continue — Break out of loops
- [P] quietly — Quietly and noisily perform Stata command
- [P] varabbrev — Control variable abbreviation
- [U] 9 The Break key
Most Stata commands allow the use of the by prefix; see [D] by. For example, the syntax diagram for the `regress` command could be presented as

```
[ by varlist: ] regress ...
```

This entry describes the writing of programs (ado-files) so that they will allow the use of Stata’s by varlist: prefix; see [D] by. If you take no special actions and write the program `myprog`, then `by varlist:` cannot be used with it:

```
. by foreign: myprog
myprog may not be combined with by r(190);
```

By reading this entry, you will learn how to modify your program so that by does work with it:

```
. by foreign: myprog
```

---

```
-> foreign = Domestic
(output for first by-group appears )
```

```
-> foreign = Foreign
(output for first by-group appears )
```

```
.
```

Syntax

```
program [ define ] program_name

[, ... byable(recall[, noheader] | onecall) ]
```

Option

`byable(recall[, noheader] | onecall)` specifies that the program is to allow the by prefix to be used with it and specifies the style in which the program is coded.

There are two supported styles, known as `byable(recall)` and `byable(onecall)`. `byable(recall)` programs are usually—not always—easier to write and `byable(onecall)` programs are usually—not always—faster.

`byable(recall)` programs are executed repeatedly, once per by group. `byable(onecall)` programs are executed only once and it is the program’s responsibility to handle the implications of the by prefix if it is specified.

`byable(recall, noheader)` programs are distinguished from `byable(recall)` programs in that by will not display a by-group header before each calling of the program.

`byable(onecall)` programs are required to handle the by...: prefix themselves, including displaying the header should they wish that. See Remarks and examples for details.
Remarks and examples

Remarks are presented under the following headings:

byable(recall) programs
Using sort in byable(recall) programs
Byable estimation commands
byable(onecall) programs
Using sort in byable(onecall) programs
Combining byable(onecall) with byable(recall)
The by-group header

If you have not read [P] sortpreserve, please do so.

Programs that are written to be used with by varlist: are said to be “byable”. Byable programs do not require the use of by varlist:, they merely allow it. There are two ways that programs can be made byable, known as byable(recall) and byable(onecall).

byable(recall) is easy to use and is sufficient for programs that report the results of calculation (class-1 programs as defined in [P] sortpreserve). byable(recall) is the method most commonly used to make programs byable.

byable(onecall) is more work to program and is intended for use in all other cases (class-2 and class-3 programs as defined in [P] sortpreserve).

byable(recall) programs

Say that you already have written a program (ado-file) and that it works; it merely does not allow by. If your program reports the results of calculations (such as summarize, regress, and most of the other statistical commands), then probably all you have to do to make your program byable is add the byable(recall) option to its program statement. For instance, if your program statement currently reads

\begin{verbatim}
program myprog, rclass sortpreserve
   ...
end
\end{verbatim}

change it to read

\begin{verbatim}
program myprog, rclass sortpreserve byable(recall)
   ...
end
\end{verbatim}

The only change you should need to make is to add byable(recall) to the program statement. Adding byable(recall) will be the only change required if

- Your program leaves behind no newly created variables. Your program might create temporary variables in the midst of calculation, but it must not leave behind new variables for the user. If your program has a generate() option, for instance, some extra effort will be required.
- Your program uses marksample or mark to restrict itself to the relevant subsample of the data. If your program does not use marksample or mark, some extra effort will be required.

Here is how byable(recall) works: if your program is invoked with a by varlist: prefix, your program will be executed \( K \) times, where \( K \) is the number of by-groups formed by the by-variables. Each time your program is executed, marksample will know to mark out the observations that are not being used in the current by-group.
Therein is the reason for the two guidelines on when you need to include only `byable(recall)` to make `by varlist: work`:

- If your program creates permanent, new variables, then it will create those variables when it is executed for the first by-group, meaning that those variables will already exist when it is executed for the second by-group, causing your program to issue an error message.

- If your program does not use `marksample` to identify the relevant subsample of the data, then each time it is executed, it will use too many observations—it will not honor the by-group—and will produce incorrect results.

There are ways around both problems, and here is more than you need:

```plaintext
function _by() takes no arguments; returns 0 when program is not being by’d; returns 1 when program is being by’d.

function _byindex() takes no arguments; returns 1 when program is not being by’d; returns 1, 2, ... when by’d and 1st call, 2nd call, ....

function _bylastcall() takes no arguments; returns 1 when program is not being by’d and is being called with the last by-group; returns 0 otherwise.

function _byn1() takes no arguments; returns the beginning observation number of the by-group currently being executed; returns 1 if _by()==0. The value returned by _byn1() is valid only if the data have not been re-sorted since the original call to the by program.

function _byn2() takes no arguments; returns the ending observation number of the by-group currently being executed; returns 1 if _by()==0. The value returned by _byn2() is valid only if the data have not been re-sorted since the original call to the by program.

macro `_byindex’ contains nothing when program is not being by’d; contains name of temporary variable when program is being by’d: variable contains 1, 2, ... for each observation in data and recorded value indicates to which by-group each observation belongs.

macro `_byvars’ contains nothing when program is not being by’d; contains names of the actual by-variables otherwise.

macro `_byrc0’ contains “, rc0” if the rc0 option is specified; contains nothing otherwise.
```

So let’s consider the problems one at a time, beginning with the second problem. Your program does not use `marksample`, and we will assume that your program has good reason for not doing so, because the easy fix would be to use `marksample`. Still, your program must somehow be determining which observations to use, and we will assume that you are creating a ‘touse’ temporary variable containing 0 if the observation is to be omitted from the analysis and 1 if it is to be used. Somewhere, early in your program, you are setting the ‘touse’ variable. Right after that, make the following addition (shown in bold):

```plaintext
program ..., ... byable(recall)
    ...
    if _by() { 
        quietly replace ‘touse’ = 0 if ‘_byindex’ != _byindex()
    }
    ...
end
```

The fix is easy: you ask if you are being by’d and, if so, you set ‘touse’ to 0 in all observations for which the value of ‘byindex’ is not equal to the by-group you are currently considering, namely, `_byindex()`.
The first problem is also easy to fix. Say that your program has a `generate(newvar)` option. Your code must therefore contain

```
program ..., ...

... if "generate" != "" {
    ... }

end
```

Change the program to read

```
program ..., ... byable(recall)

... if "generate" != "" & _bylastcall() {
    ... }

end
```

_bylastcall()_ will be 1 (meaning true) whenever your program is not being by’d and, when it is being by’d, whenever the program is being executed for the last by-group. The result is that the new variable will be created containing only the values for the last by-group, but with a few exceptions, that is how all of Stata works. Alternatives are discussed under `byable(onecall)`.

All the other macros and functions that are available are for creating special effects and are rarely used in `byable(recall)` programs.

### Using sort in `byable(recall)` programs

You may use `sort` freely within `byable(recall)` programs, and in fact, you can use any other Stata command you wish; there are simply no issues. You may even use `sortpreserve` to restore the sort order at the conclusion of your program; see [P] `sortpreserve`.

We will discuss the issue of `sort` in depth just to convince you that there is nothing with which you must be concerned.

When a `byable(recall)` program receives control and is being by’d, the data are guaranteed to be sorted by ‘‘byvars’’ only when _byindex() = 1—only on the first call. If the program re-sorts the data, the data will remain re-sorted on the second and subsequent calls, even if `sortpreserve` is specified. This may sound like a problem, but it is not. `sortpreserve` is not being ignored; the data will be restored to their original order after the final call to your program. Let’s go through the two cases: either your program uses `sort` or it does not.

1. If your program needs to use `sort`, it will probably need a different sort order for each by-group. For instance, a typical program that uses `sort` will include lines such as

   ```
sort ‘touse’ ‘id’...
```

   and so move the relevant sample to the top of the dataset. This `byable(recall)` program makes no reference to the ‘‘byvars’’ themselves, nor does it do anything differently when the by prefix is specified and when it is not. That is typical; `byable(recall)` programs rarely find it necessary to refer to the ‘‘byvars’’ directly.

In any case, because this program is sorting the data explicitly every time it is called (and we know it must be because `byable(recall)` programs are executed once for each by-group), there is no reason for Stata to waste its time restoring a sort order that will just be undone anyway. The original sort order needs to be reestablished only after the final call.
2. The other alternative is that the program does not use \texttt{sort}. Then it is free to exploit that the data are sorted on \texttt{byvars}'. Because the data will be sorted on the first call, the program does no \texttt{sort}s, so the data will be sorted on the second call, and so on. \texttt{byable(recall)} programs rarely exploit the sort order, but the program is free to do so.

\textbf{Byable estimation commands}

Estimation commands are natural candidates for the \texttt{byable(recall)} approach. There is, however, one issue that requires special attention. Estimation commands really have two syntaxes: one at the time of estimation,

\begin{verbatim}
[\texttt{prefix_command} :] \texttt{estcmd varlist ... [, estimation_options replay_options]}
\end{verbatim}

and another for redisplaying results:

\begin{verbatim}
\texttt{estcmd [ , replay_options ]}
\end{verbatim}

With estimation commands, \texttt{by} is not allowed when results are redisplayed. We must arrange for this in our program, and that is easy enough. The general outline for an estimation command is

\begin{verbatim}
program \texttt{estcmd, ...}
  if \texttt{replay}() {
    if \texttt{"e(cmd)"}!="estcmd" \texttt{error 301}
    \texttt{syntax [ , replay_options]}
  }
  else {
    \texttt{syntax ... [ , estimation_options replay_options]}
    \texttt{...estimation logic...}
  }
...\texttt{display logic...}
\end{verbatim}

and to this, we make the changes shown in bold:

\begin{verbatim}
program \texttt{estcmd, ... byable(recall)}
  if \texttt{replay}() {
    if \texttt{"e(cmd)"}!="estcmd" \texttt{error 301}
      \texttt{if \_by() error 190}
    \texttt{syntax [ , replay_options]}
  }
  else {
    \texttt{syntax ... [ , estimation_options replay_options]}
    \texttt{...estimation logic...}
  }
...\texttt{display logic...}
\end{verbatim}

In addition to adding \texttt{byable(recall)}, we add the line

\begin{verbatim}
if \_by() \texttt{error 190}
\end{verbatim}

in the case where we have been asked to redisplay results. If we are being by'd (if \_by() is true), then we issue error 190 (request may not be combined with \texttt{by}).
byable(onecall) programs

byable(onecall) requires more work to use. We strongly recommend using byable(recall) whenever possible.

The main use of byable(onecall) is to create programs such as generate and egen, which allow the by prefix but operate on all the data and create a new variable containing results for all the different by-groups.

byable(onecall) programs are, as the name implies, executed only once. The byable(onecall) program is responsible for handling all the issues concerning the by, and it is expected to do that by using

```
function _by() takes no arguments
returns 0 when program is not being by’d
returns 1 when program is being by’d

macro ‘_byvars’ contains nothing when program is not being by’d
contains names of the actual by-variables otherwise

macro ‘_byrc0’ contains nothing or “rc0”
contains “, rc0” if by’s rc0 option was specified
```

In byable(onecall) programs, you are responsible for everything, including the output of by-group headers if you want them.

The typical candidates for byable(onecall) are programs that do something special and odd with the by-variables. We offer the following guidelines:

1. Ignore that you are going to make your program byable when you first write it. Instead, include a by() option in your program. Because your program cannot be coded using byable(recall), you already know that the by-variables are entangled with the logic of your routine. Make your program work before worrying about making it byable.
2. Now go back and modify your program. Include byable(onecall) on the program statement line. Remove by(varlist) from your syntax statement, and immediately after the syntax statement, add the line

   `local by "’_byvars’"

3. Test your program. If it worked before, it will still work now. To use the by() option, you put the by varlist: prefix out front.
4. Ignore the macro ‘_byrc0’. Byable programs rarely do anything different when the user specifies by’s rc0 option.

Using sort in byable(onecall) programs

You may use sort freely within byable(onecall) programs. You may even use sortpreserve to restore the sort order at the conclusion of your program.

When a byable(onecall) program receives control and is being by’d, the data are guaranteed to be sorted by ‘_byvars’.
Combining byable(onecall) with byable(recall)

byable(onecall) can be used as an interface to other byable programs. Let’s pretend that you are writing a command—we will call it switcher—that calls one of two other commands based perhaps on some aspect of what the user typed or, perhaps, based on what was previously estimated. The rule by which switcher decides to call one or the other does not matter for this discussion; what is important is that switcher switches between what we will call prog1 and prog2. prog1 and prog2 might be actual Stata commands, Stata commands that you have written, or even subroutines of switcher.

We will further imagine that prog1 and prog2 have been implemented using the byable(recall) method and that we now want switcher to allow the by prefix, too. The easy way to do that is

```
program switcher, byable(onecall)
    if _by() {
        local by "by ‘_byvars’ ‘_byrc0’:"
    }
    if (whatever makes us decide in favor of prog1) {
        ‘by’ prog1 ‘0’
    } else ‘by’ prog2 ‘0’
end
```

switcher works by re-creating the by varlist: prefix in front of prog1 or prog2 if by was specified. switcher will be executed only once, even if by was specified. prog1 and prog2 will be executed repeatedly.

In the above outline, it is not important that prog1 and prog2 were implemented using the byable(recall) method. They could just as well be implemented using byable(onecall), and switcher would change not at all.

The by-group header

Usually, when you use a command with by, a header is produced above each by-group:

```
. by foreign: summarize mpg weight

-> foreign = Domestic
   (output for first by-group appears)

-> foreign = Foreign
   (output for first by-group appears)
```

The by-group header does not always appear:

```
. by foreign: generate new = sum(mpg)
```

When you write your own programs, the header will appear by default if you use byable(recall) and will not appear if you use byable(onecall).

If you want the header and use byable(onecall), you will have to write the code to output it.
If you do not want the header and use byable(recall), you can specify byable(recall, noheader):

```
program ..., ... byable(recall, noheader)
  ...
end
```

**Description**

`capture` executes `command`, suppressing all its output (including error messages, if any) and issuing a return code of zero. The actual return code generated by `command` is stored in the built-in scalar `_rc`.

`capture` can be combined with `{}` to produce capture blocks, which suppress output for the block of commands. See the technical note following example 6 for more information.

**Syntax**

```
capture [ : ] command

capture {
            stata_commands
        }
```

**Remarks and examples**

`capture` is useful in do-files and programs because their execution terminates when a command issues a nonzero return code. Preceding sensitive commands with the word `capture` allows the do-file or program to continue despite errors. Also do-files and programs can be made to respond appropriately to any situation by conditioning their remaining actions on the contents of the scalar `_rc`.

### Example 1

You will never have cause to use `capture` interactively, but an interactive experiment will demonstrate what `capture` does:

```
. drop _all
. list myvar
   no variables defined
   r(111);
. capture list myvar
. display _rc
   111
```
When we said *list myvar*, we were told that we had no variables defined and got a return code of 111. When we said *capture list myvar*, we got no output and a zero return code. First, you should wonder what happened to the message “no variables defined”. *capture* suppressed that message. It suppresses all output produced by the command it is capturing. Next we see no return code message, so the return code was zero. We already know that typing *list myvar* generates a return code of 111, so *capture* suppressed that, too.

*capture* places the return code in the built-in scalar `rc`. When we display the value of this scalar, we see that it is 111.

**Example 2**

Now that we know what *capture* does, let’s put it to use. *capture* is used in programs and do-files. Sometimes you will write programs that do not care about the outcome of a Stata command. You may want to ensure, for instance, that some variable does not exist in the dataset. You could do so by including *capture drop result*.

If *result* exists, it is now gone. If it did not exist, *drop* did nothing, and its nonzero return code and the error message have been intercepted. The program (or do-file) continues in any case. If you have written a program that creates a variable named *result*, it would be good practice to begin such a program with *capture drop result*. This way, you could use the program repeatedly without having to worry whether the *result* variable already exists.

**Technical note**

When combining *capture* and *drop*, never say something like *capture drop var1 var2 var3*. Remember that Stata commands do either exactly what you say or nothing at all. We might think that our command would be guaranteed to eliminate *var1*, *var2*, and *var3* from the data if they exist. It is not. Imagine that *var3* did not exist in the data. *drop* would then do nothing. It would not *drop var1* and *var2*. To achieve the desired result, we must give three commands:

```
capture drop var1
capture drop var2
capture drop var3
```

**Example 3**

Here is another example of using *capture* to dispose of nonzero return codes: When using do-files to define programs, it is common to begin the definition with *capture program drop progname* and then put *program progname*. This way, you can rerun the do-file to load or reload the program.

**Example 4**

Let’s consider programs whose behavior is contingent upon the outcome of some command. You write a program and want to ensure that the first argument (the macro ‘1’) is interpreted as a new variable. If it is not, you want to issue an error message:
You use the `confirm` command to determine if the variable already exists and then condition your error message on whether `confirm` thinks ‘1’ can be a new variable. We did not have to go to the trouble here. `confirm` would have automatically issued the appropriate error message, and its nonzero return code would have stopped the program anyway.

Example 5

As before, you write a program and want to ensure that the first argument is interpreted as a new variable. This time, however, if it is not, you want to use the name `_answer` in place of the name specified by the user:

```stata
capture confirm new variable '1'
if _rc!=0 {
    local 1 _answer
    confirm new variable '1'
}
(program continues...)
```

Example 6

There may be instances where you want to capture the return code but not the output. You do that by combining `capture` with `noisily`. For instance, we might change our program to read

```stata
capture noisily confirm new variable '1'
if _rc!=0 {
    local 1 _answer
    display "I’ll use _answer"
}
(program continues...)
```

`confirm` will generate some message such as “…already exists”, and then we will follow that message with “I’ll use _answer”.

Technical note

`capture` can be combined with `{}` to produce `capture blocks`. Consider the following:

```stata
capture {
    confirm var ‘1’
    confirm integer number ‘2’
    confirm number ‘3’
}
if _rc!=0 {
    display "Syntax is variable integer number"
    exit 198
}
(program continues...)
```
If any of the commands in the capture block fail, the subsequent commands in the block are aborted, but the program continues with the if statement.

Capture blocks can be used to intercept the Break key, as in

```stata
capture {
    stata_commands
}
if _rc==1 {
    Break key cleanup code
    exit 1
}
(program continues...)
```

Remember that Break always generates a return code of 1. There is no reason, however, to restrict the execution of the cleanup code to Break only. Our program might fail for some other reason, such as insufficient room to add a new variable, and we would still want to engage in the cleanup operations. A better version would read

```stata
capture {
    stata_commands
}
if _rc!=0 {
    local oldrc = _rc
    Break key and error cleanup code
    exit 'oldrc'
}
(program continues...)
```

⚠️ Technical note

If, in our program above, the stata_commands included an exit or an exit 0, the program would terminate and return 0. Neither the cleanup nor the program continues code would be executed. If stata_commands included an exit 198, or any other exit that sets a nonzero return code, however, the program would not exit. capture would catch the nonzero return code, and execution would continue with the cleanup code.

[U] 18.2 Relationship between a program and a do-file
char — Characteristics

Description

See [U] 12.8 Characteristics for a description of characteristics. These commands allow manipulating characteristics.

Syntax

Define characteristics

```
char [ define] evarname[charname] ["text"]
```

List characteristics

```
char list [evarname[charname]]
```

Rename characteristics

```
char rename oldvar newvar [, replace]
```

Also related is

```
{local|global} mname: char evarname[charname]
```

evarname is a variable name or _dta and charname is a characteristic name. In the syntax diagrams, distinguish carefully between [], which you type, and [ ], which indicates that the element is optional.

Option

replace (for use only with char rename) specifies that if characteristics of the same name already exist, they are to be replaced. replace is a seldom-used, low-level, programmer’s option.

char rename oldvar newvar moves all characteristics of oldvar to newvar, leaving oldvar with none and newvar with all the characteristics oldvar previously had. char rename oldvar newvar moves the characteristics, but only if newvar has no characteristics with the same name. Otherwise, char rename produces the error message that newvar[whatever] already exists.

Remarks and examples

We begin by showing how the commands work mechanically and then continue to demonstrate the commands in more realistic situations.
char define sets and clears characteristics, although there is no reason to type `define`:

- char _dta[one] this is char named one of _dta
- char _dta[two] this is char named two of _dta
- char mpg[one] this is char named one of mpg
- char mpg[two] "this is char named two of mpg"
- char mpg[three] "this is char named three of mpg"

Whether we include the double quotes does not matter. You clear a characteristic by defining it to be nothing:

- char mpg[three]

`char list` is used to list existing characteristics; it is typically used for debugging:

- char list
  _dta[two] : this is char named two of _dta
  _dta[one] : this is char named one of _dta
  mpg[two] : this is char named two of mpg
  mpg[one] : this is char named one of mpg

- char rename mpg weight

- char list
  _dta[two] : this is char named two of _dta
  _dta[one] : this is char named one of _dta
  weight[two] : this is char named two of mpg
  weight[one] : this is char named one of mpg

- char rename weight mpg // put it back

The contents of specific characteristics may be obtained in the same way as local macros by referring to the characteristic name between left and right single quotes; see [U] 12.8 Characteristics.

- display "'mpg[one]'"
  this is char named one of mpg
- display "'_dta[]'"
  two one

Referring to a nonexisting characteristic returns a null string:

- display "the value is |'mpg[three]'|
  the value is ||
How to program with characteristics

Example 1

You are writing a program that requires the value of the variable recording “instance” (first time, second time, etc.). You want your command to have an option `ins(varname)`, but after the user has specified the variable once, you want your program to remember it in the future, even across sessions. An outline of your program is

```stata
program ... 
  version 15.0 
  syntax ... [, ... ins(varname) ... ] 
  ... 
  if "'ins'"=="" { 
    local ins "'_dta[Instance]'" 
  } 
  confirm variable 'ins' 
  char _dta[Instance] : 'ins' 
  ... 
end
```

Example 2

You write a program, and among other things, it changes the contents of one of the variables in the user’s data. You worry about the user pressing `Break` while the program is in the midst of the change, so you correctly decide to construct the replaced values in a temporary variable and, only at the conclusion, drop the user’s original variable and replace it with the new one. In this example, macro `uservar` contains the name of the user’s original variable. Macro `newvar` contains the name of the temporary variable that will ultimately replace it.

The following issues arise when you duplicate the original variable: you want the new variable to have the same variable label, the same value label, the same format, and the same characteristics.

```stata
program ... 
  version 15.0 
  ... 
  tempvar newvar 
  ... 
  (code creating 'newvar') 
  ... 
  local varlab : variable label 'uservar' 
  local vallab : value label 'uservar' 
  local format : format 'uservar' 
  label var 'newvar' "'varlab'" 
  label values 'newvar' 'vallab' 
  format 'newvar' 'format' 
  char rename 'uservar' 'newvar' 
  drop 'uservar' 
  rename 'newvar' 'uservar' 
end
```

You are supposed to notice the `char rename` command included to move the characteristics originally attached to `uservar` to `newvar`. See `[P] macro`, `[D] label`, and `[D] format` for information on the commands preceding the `char rename` command.
This code is almost perfect, but if you are really concerned about the user pressing \textit{Break}, there is a potential problem. What happens if the user presses \textit{Break} between the \texttt{char rename} and the final \texttt{rename}? The last three lines would be better written as

```plaintext
nobreak {
    char rename 'uservar' 'newvar'
    drop 'uservar'
    rename 'newvar' 'uservar'
}
```

Now even if the user presses \textit{Break} during these last three lines, it will be ignored; see \cite{break}.

Description

Stata’s two programming languages, ado and Mata, each support object-oriented programming. This manual entry explains object-oriented programming in ado. Most users interested in object-oriented programming will wish to do so in Mata. See [M-2] class to learn about object-oriented programming in Mata.

Ado classes are a programming feature of Stata that are especially useful for dealing with graphics and GUI problems, although their use need not be restricted to those topics. Ado class programming is an advanced programming topic and will not be useful to most programmers.

Appendix A. Finding, loading, and clearing class definitions
Appendix B. Jargon
1. Introduction

A class is a collection of member variables and member programs. The member programs of a class manipulate or make calculations based on the member variables. Classes are defined in .class files. For instance, we might define the class coordinate in the file coordinate.class:

```
begin coordinate.class
version 15.0
class coordinate {
    double x
    double y
}
program .set
    args x y
    .x = 'x'
    .y = 'y'
end
```

The above file does not create anything. It merely defines the concept of a “coordinate”. Now that the file exists, however, you could create a “scalar” variable of type coordinate by typing

```
 coord = .coordinate.new
```

.coord is called an instance of coordinate; it contains .coord.x (a particular x coordinate) and .coord.y (a particular y coordinate). Because we did not specify otherwise, .coord.x and .coord.y contain missing values, but we could reset .coord to contain (1,2) by typing

```
.coord.x = 1
.coord.y = 2
```

Here we can do that more conveniently by typing

```
.coord.set 1 2
```

because coordinate.class provides a member program called .set that allows us to set the member variables. There is nothing especially useful about .set; we wrote it mainly to emphasize that classes could, in fact, contain member programs. Our coordinate.class definition would be nearly as good if we deleted the .set program. Classes are not required to have member programs, but they may.

If we typed

```
.coord2 = .coordinate.new
.coord2.set 2 4
```

we would now have a second instance of a coordinate, this one named .coord2, which would contain (2,4).
Now consider another class, line.class:

```
begin line.class

version 15.0
class line {
    coordinate c0
    coordinate c1
}
program .set
    args x0 y0 x1 y1
    .c0.set 'x0' 'y0'
    .c1.set 'x1' 'y1'
end
program .length
    class exit sqrt(('.c0.y'-'c1.y')^2 + ('.c0.x'-'c1.x')^2)
end
program .midpoint
    local cx = ('.c0.x' + '.c1.x')/2
    local cy = ('.c0.y' + '.c1.y')/2
    tempname b
    .'b'=.coordinate.new
    .'b'.set 'cx' 'cy'
    class exit .'b'
end
```

Like coordinate.class, line.class has two member variables—named .c0 and .c1—but rather than being numbers, .c0 and .c1 are coordinates as we have previously defined the term. Thus the full list of the member variables for line.class is:

- .c0 first coordinate
- .c0.x x value (a double)
- .c0.y y value (a double)
- .c1 second coordinate
- .c1.x x value (a double)
- .c1.y y value (a double)

If we typed

```
.li = .line.new
```

we would have a line named .li in which

```
.li.c0 first coordinate of line .li
.li.c0.x x value (a double)
.li.c0.y y value (a double)
.li.c1 second coordinate of line .li
.li.c1.x x value (a double)
.li.c1.y y value (a double)
```

What are the values of these variables? Because we did not specify otherwise, .li.c0 and .li.c1 will receive default values for their type, coordinate. That default is (...) because we did not specify otherwise when we defined lines or coordinates. Therefore, the default values are (...) and (...), and we have a missing line.

As with coordinate, we included the member function .set to make setting the line easier. We can type

```
.li.set 1 2 2 4
```

and we will have a line going from (1,2) to (2,4).
line.class contains the following member programs:

- .set program to set .c0 and .c1
- .c0.set program to set .c0
- .c1.set program to set .c1
- .length program to return length of line
- .midpoint program to return coordinate of midpoint of line

.set, .length, and .midpoint came from line.class. .c0.set and .c1.set came from coordinate.class.

Member program .length returns the length of the line.

    .len = .li.length

would create .len containing the result of .li.length. The result of running the program .length on the object .li. .length returns a double, and therefore, .len will be a double.

.Member program .midpoint returns the midpoint of a line.

    .mid = .li.midpoint

would create .mid containing the result of .li.midpoint, the result of running the program .midpoint on the object .li. .midpoint returns a coordinate, and therefore, .mid will be a coordinate.

2. Definitions

2.1 Class definition

Class classname is defined in file classname.class. The definition does not create any instances of the class.

The classname.class file has three parts:

```plaintext
begin classname.class
version ...
// Part 1: version statement
class  classname {  // Part 2: declaration of member variables
    ...
}
program ...
// Part 3: code for member programs
end
program ...
...
end
...
```

end classname.class

2.2 Class instance

To create a “variable” name of type classname, you type

    .name = .classname.new
After that, \textit{name} is variously called an identifier, class variable, class instance, object, object instance, or sometimes just an instance. Call it what you will, the above creates new \textit{name}—or replaces existing \textit{name}—to contain the result of an application of the definition of \textit{classname}. And, just as with any variable, you can have many different variables with many different names all the same type.

\textit{name} is called a first-level or top-level identifier. \textit{name1.name2} is called a second-level identifier, and so on. Assignment into top-level identifiers is allowed if the identifier does not already exist or if the identifier exists and is of type \textit{classname}. If the top-level identifier already exists and is of a different type, you must drop the identifier first and then re-create it; see \textit{11. Object destruction}.

Consider the assignment

\begin{verbatim}
.name1.name2 = .classname.new
\end{verbatim}

The above statement is allowed if \textit{name1} already exists and if \textit{name2} is declared, in \textit{name1}'s class definition, to be of type \textit{classname}. In that case, \textit{name1.name2} previously contained a \textit{classname} instance and now contains a \textit{classname} instance, the difference being that the old contents were discarded and replaced with the new ones. The same rule applies to third-level and higher identifiers.

Classes, and class instances, may also contain member programs. Member programs are identified in the same way as class variables. \textit{name1.name2} might refer to a member variable or to a member program.

\section*{2.3 Class context}

When a class program executes, it executes in the context of the current instance. For example, consider the instance creation

\begin{verbatim}
.mycoord = .coordinate.new
\end{verbatim}

and recall that \textit{coordinate.class} provides member program \textit{.set}, which reads

\begin{verbatim}
program .set
    args x y
    .x = 'x'
    .y = 'y'
end
\end{verbatim}

Assume that we type \texttt{".mycoord.set 2 4"}. When \textit{.set} executes, it executes in the context of \textit{.mycoord}. In the program, the references to \texttt{x} and \texttt{y} are assumed to be to \textit{.mycoord.x} and \textit{.mycoord.y}. If we typed \texttt{".other.set"}, the references would be to \textit{.other.x} and \textit{.other.y}.

Look at the statement \texttt{".x = 'x'"} in \textit{.set}. Pretend that \texttt{'x'} is 2 so that, after macro substitution, the statement reads \texttt{".x = 2"}. Is this a statement that the first-level identifier \texttt{.x} is to be set to 2? No, it is a statement that \textit{.impliedcontext.x} is to be set to 2. The same would be true whether \texttt{.x} appeared to the right of the equal sign or anywhere else in the program.

The rules for resolving things like \texttt{x} and \texttt{y} are actually more complicated. They are resolved to the implied context if they exist in the implied context, and otherwise they are interpreted to be in the global context. Hence, in the above examples, \texttt{x} and \texttt{y} were interpreted as being references to \textit{.impliedcontext.x} and \textit{.impliedcontext.y} because \texttt{x} and \texttt{y} existed in \textit{.impliedcontext}. If, however, our program made a reference to \texttt{.c}, that would be assumed to be in the global context (that is, to be just \texttt{.c}), because there is no \texttt{.c} in the implied context. This is discussed at length in \textit{9. Prefix operators}.

If a member program calls a regular program—a regular ado-file—that program will also run in the same class context; for example, if \textit{.set} included the lines

\begin{verbatim}
...
move_to_right
  .x = r(x)
  .y = r(y)

and program move_to_right.ado had lines in it referring to .x and .y, they would be interpreted as .impliedcontext.x and .impliedcontext.y.

In all programs—member programs or ado-files—we can explicitly control whether we want identifiers in the implied context or globally with the .Local and .Global prefixes; see 9. Prefix operators.

3. Version control

The first thing that should appear in a .class file is a version statement; see [P] version. For example, coordinate.class reads

```
version 15.0
[ class statement defining member variables omitted ]
program .set
    args x y
    .x = "x"
    .y = "y"
end
```

The version 15.0 at the top of the file specifies not only that, when the class definition is read, it be interpreted according to version 15.0 syntax, but also that when each of the member programs runs, it be interpreted according to version 15.0. Thus you do not need to include a version statement inside the definition of each member program, although you may if you want that one program to run according to the syntax of a different version of Stata.

Including the version statement at the top, however, is of vital importance. Stata is under continual development, and so is the class subsystem. Syntax and features can change. Including the version command ensures that your class will continue to work as you intended.

4. Member variables

4.1 Types

The second thing that appears in a .class file is the definition of the member variables. We have seen two examples:

```
version 15.0
class coordinate {  
    double x  
    double y  
}
[ member programs omitted ]
```

and
In the first example, the member variables are .x and .y, and in the second, .c0 and .c1. In the first example, the member variables are of type double, and in the second, of type coordinate, another class.

The member variables may be of type

- **double**: double-precision scalar numeric value, which includes missing values ., .a, ..., and .z
- **string**: scalar string value, with minimum length 0 (""") and maximum length the same as for macros, in other words, long

The class **string** type is different from Stata’s **str#** and **strL** types. It can hold much longer string values than can the **str#** type, but not as long of string values as the **strL** type. Additionally, unlike **strL**s, class **strings** cannot contain binary 0.

A class definition might read

```
version 15.0
begin todolist.class

class todolist {
    double n // number of elements in list
    string name // who the list is for
    array list // the list itself
    actions x // things that have been done
}
end todolist.class
```

In the above, **actions** is a class, not a primitive type. Somewhere else, we have written **actions.class**, which defines what we mean by **actions**.

**arrays** are not typed when they are declared. An **array** is not an array of doubles or an array of strings or an array of **coordinates**; rather, each array element is separately typed at run time, so an array may turn out to be an array of doubles or an array of strings or an array of **coordinates**, or it may turn out that its first element is a **double**, its second element is a **string**, its third element is a **coordinate**, its fourth element is something else, and so on.

Similarly, **arrays** are not declared to be of a predetermined size. The size is automatically determined at run time according to how the array is used. Also arrays can be sparse. The first element of an array might be a **double**, its fourth element a **coordinate**, and its second and third elements left undefined. There is no inefficiency associated with this. Later, a value might be assigned to the fifth element of the array, thus extending it, or a value might be assigned to the second and third elements, thus filling in the gaps.
4.2 Default initialization

When an instance of a class is created, the member variables are filled in as follows:

- **double** : (missing value)
- **string** : ""
- **classname** : as specified by class definition
- **array** : empty, an array with no elements yet defined

4.3 Specifying initialization

You may specify in `classname.class` the initial values for member variables. To do this, you type an equal sign after the identifier, and then you type the initial value. For example,

```plaintext
todolist.class
version 15.0
class todolist {
  double n = 0
  string name = "nobody"
  array list = {"show second syntax", "mark as done"}
  actions x = .actions.new arguments
}
```

The initialization rules are as follows:

- **double** `membervarname = ...`:
  After the equal sign, you may type any number or expression. To initialize the member variable with a missing value (., .a, .b, ..., .z), you must enclose the missing value in parentheses. Examples include
  ```plaintext
double n = 0
double a = (.)
double b = (.b)
double z = (2+3)/sqrt(5)
```
  Alternatively, after the equal sign, you may specify the identifier of a member variable to be copied or program to be run as long as the member variable is a `double` or the program returns a `double`. If a member program is specified that requires arguments, they must be specified following the identifier. Examples include
  ```plaintext
double n = .clearcount
double a = .gammavalue 4 5 2
double b = .color.cvalue, color(green)
```
  The identifiers are interpreted in terms of the global context, not the class context being defined. Thus `.clearcount`, `.gammavalue`, and `.color.cvalue` must exist in the global context.

- **string** `membervarname = ...`:
  After the equal sign, you type the initial value for the member variable enclosed in quotes, which may be either simple (" and ") or compound (‘" and "’). Examples include
  ```plaintext
  string name = "nobody"
  string s = "quotes "inside" strings"
  string a = ""
  ```
You may also specify a string expression, but you must enclose it in parentheses. For example,

```plaintext
string name = ("no" + "body")
string b   = (char(11))
```

Or you may specify the identifier of a member variable to be copied or a member program to be run, as long as the member variable is a string or the program returns a string. If a member program is specified that requires arguments, they must be specified following the identifier. Examples include

```plaintext
string n = .defaultname
string a = .recapitalize "john smith"
string b = .names.defaults, category(null)
```

The identifiers are interpreted in terms of the global context, not the class context being defined. Thus .defaultname, .recapitalize, and .names.defaults must exist in the global context.

```plaintext
array membervarname = {...}
```

After the equal sign, you type the set of elements in braces ({} and {}), with each element separated from the next by a comma.

If an element is enclosed in quotes (simple or compound), the corresponding array element is defined to be string with the contents specified.

If an element is a literal number excluding ., .a, ..., and .z, the corresponding array element is defined to be double and filled in with the number specified.

If an element is enclosed in parentheses, what appears inside the parentheses is evaluated as an expression. If the expression evaluates to a string, the corresponding array element is defined to be string and the result is filled in. If the expression evaluates to a number, the corresponding array element is defined to be double and the result is filled in. Missing values may be assigned to array elements by being enclosed in parentheses.

An element that begins with a period is interpreted as an object identifier in the global context. That object may be a member variable or a member program. The corresponding array element is defined to be of the same type as the specified member variable or of the same type as the member program returns. If a member program is specified that requires arguments, the arguments must be specified following the identifier, but the entire syntactical elements must be enclosed in square brackets ([ and ]).

If the element is nothing, the corresponding array element is left undefined.

Examples include

```plaintext
array mixed = {1, 2, "three", 4}
array els   = {.box.new, , .table.new}
array rad   = {[.box.new 2 3], , .table.new}
```

Note the double commas in the last two initializations. The second element is left undefined. Some programmers would code

```plaintext
array els   = {.box.new, /*nothing*/, .table.new}
array rad   = {[.box.new 2 3], /*nothing*/, .table.new}
```

to emphasize the null initialization.
After the equal sign, you specify the identifier of a member variable to be copied or a member program to be run, as long as the member variable is of type `classname` or the member program returns something of type `classname`. If a member program is specified that requires arguments, they must be specified following the identifier. In either case, the identifier will be interpreted in the global context. Examples include

```
box mybox1 = .box.new
box mybox2 = .box.new 2 4 7 8, tilted
```

All the types can be initialized by copying other member variables or by running other member programs. These other member variables and member programs must be defined in the global context and not the class context. In such cases, each initialization value or program is, in fact, copied or run only once—at the time the class definition is read—and the values are recorded for future use. This makes initialization fast. This also means, however, that

- If, in a class definition called, say, `border.class`, you defined a member variable that was initialized by `.box.new`, and if `.box.new` counted how many times it is run, then even if you were to create 1,000 instances of `border`, you would discover that `.box.new` was run only once. If `.box.new` changed what it returned over time (perhaps because of a change in some state of the system being implemented), the initial values would not change when a new border object was created.

- If, in `border.class`, you were to define a member variable that is initialized as `.system.curvals.no_of_widgets`, which we will assume is another member variable, then even if `.system.curvals.no_of_widgets` were changed, the new instances of `border.class` would always have the same value—the value of `.system.curvals.no_of_widgets` current at the time `border.class` was read.

In both of the above examples, the method just described—the prerecorded assignment method of specifying initial values—would be inadequate. The method just described is suitable for specifying constant initial values only.

### 4.4 Specifying initialization 2, `.new`

Another way to specify how member variables are to be initialized is to define a `.new` program within the class.

To create a new instance of a class, you type

```
  .name = .classname .new
```

`.new` is, in fact, a member program of `classname`; it is just one that is built in, and you do not have to define it to use it. The built-in `.new` allocates the memory for the instance and fills in the default or specified initial values for the member variables. If you define a `.new`, your `.new` will be run after the built-in `.new` finishes its work.

For example, our example `coordinate.class` could be improved by adding a `.new` member program:
version 15.0
class coordinate {
    double x
    double y
}
program .new
    if "'0'" != "" {
        .set '0'
    }
end
program .set
    args x y
    .x = 'x'
    .y = 'y'
end

With this addition, we could type

    .coord = .coordinate.new
    .coord.set 2 4

or we could type

    .coord = .coordinate.new 2 4

We have arranged .new to take arguments—optional ones here—that specify where the new point is to be located. We wrote the code so that .new calls .set, although we could just as well have written the code so that the lines in .set appeared in .new and then deleted the .set program. In fact, the two-part construction can be desirable because then we have a function that will reset the contents of an existing class as well.

In any case, by defining your own .new, you can arrange for any sort of complicated initialization of the class, and that initialization can be a function of arguments specified if that is necessary.

The .new program need not return anything; see 6. Member programs’ return values.

.new programs are not restricted just to filling in initial values. They are programs that you can code however you wish. .new is run every time a new instance of a class is created with one exception: when an instance is created as a member of another instance (in which case, the results are prerecorded).

4.5 another way of declaring

In addition to the syntax

    type name [ = initialization ]

where type is one of double, string, classname, or array, there is an alternative syntax that reads

    name = initialization

That is, you may omit specifying type when you specify how the member variable is to be initialized because, then, the type of the member variable can be inferred from the initialization.
4.6 Scope

In the examples we have seen so far, the member variables are unique to the instance. For example, if we have

```
.coord1 = .coordinate.new
.coord2 = .coordinate.new
```

then the member variables of .coord1 have nothing to do with the member variables of .coord2. If we were to change .coord1.x, then .coord2.x would remain unchanged.

Classes can also have variables that are shared across all instances of the class. Consider

```
version 15.0
class coordinate2 {
    classwide:
        double x_origin = 0
        double y_origin = 0
    instancespecific:
        double x = 0
        double y = 0
}
```

In this class definition, .x and .y are as they were in coordinate.class—they are unique to the instance. .x_origin and .y_origin, however, are shared across all instances of the class. That is, if we were to type

```
.ac = .coordinate2.new
.bc = .coordinate2.new
```

there would be only one copy of .x_origin and of .y_origin. If we changed .x_origin in .ac,

```
.ac.x_origin = 2
```

we would find that .bc.x_origin had similarly been changed. That is because .ac.x_origin and .bc.x_origin are, in fact, the same variable.

The effects of initialization are a little different for classwide variables. In coordinate2.class, we specified that .origin_x and .origin_y both be initialized as 0, and so they were when we typed “.ac = .coordinate2.new”, creating the first instance of the class. After that, however, .origin_x and .origin_y will never be reinitialized because they need not be re-created, being shared. (That is not exactly accurate because, once the last instance of a coordinate2 has been destroyed, the variables will need to be reinitialized the next time a new first instance of coordinate2 is created.)

Classwide variables, just as with instance-specific variables, can be of any type. We can define

```
version 15.0
class supercoordinate {
    classwide:
        coordinate origin
    instancespecific:
        coordinate pt
}
```

The qualifiers classwide: and instancespecific: are used to designate the scope of the member variables that follow. When neither is specified, instancespecific: is assumed.
4.7 Adding dynamically

Once an instance of a class exists, you can add new (instance-specific) member variables to it. The syntax for doing this is

\[ \text{name .Declare attribute\_declaration} \]

where \text{name} is the identifier of an instance and \text{attribute\_declaration} is any valid attribute declaration such as

\[
\begin{align*}
\text{double} & \quad \text{varname} \\
\text{string} & \quad \text{varname} \\
\text{array} & \quad \text{varname} \\
\text{classname} & \quad \text{varname}
\end{align*}
\]

and, on top of that, we can include = and initializer information as defined in \textit{4.3 Specifying initialization} above.

For example, we might start with

\[ \text{.coord} = \text{.coordinate.new} \]

and discover that there is some extra information that we would like to carry around with the particular instance \text{.coord}. Here we want to carry around some color information that we will use later, and we have at our fingertips \text{color.class}, which defines what we mean by \text{color}. We can type

\[ \text{.coord.Declare color mycolor} \]

or even

\[ \text{.coord.Declare color mycolor} = \text{.color.new, color(default)} \]

to cause the new class instance to be initialized the way we want. After that command, \text{.coord} now contains \text{.coord.color} and whatever third-level or higher identifiers \text{color} provides. We can still invoke the member programs of \text{coordinate} on \text{.coord}, and to them, \text{.coord} will look just like a \text{coordinate} because they will know nothing about the extra information (although if they were to make a copy of \text{.coord}, then the copy would include the extra information). We can use the extra information in our main program and even in subroutines that we write.

Technical note

Just as with the declaration of member variables inside the \text{class \{}\} statement, you can omit specifying the \text{type} when you specify the initialization. In the above, the following would also be allowed:

\[ \text{.coord.Declare mycolor} = \text{.color.new, color(default)} \]
### 4.8 Advanced initialization, .oncopy

Advanced initialization is an advanced concept, and we need concern ourselves with it only when our class is storing references to items outside the class system. In such cases, the class system knows nothing about these items other than their names. We must manage the contents of these items.

Assume that our coordinates class was storing not scalar coordinates but rather the names of Stata variables that contained coordinates. When we create a copy of such a class,

```
.coord = .coordinate.new 2 4
.coordcopy = .coord
```

.coordcopy will contain copies of the names of the variables holding the coordinates, but the variables themselves will not be copied. To be consistent with how all other objects are treated, we may prefer that the contents of the variables be copied to new variables.

As with .new we can define an .oncopy member program that will be run after the default copy operation has been completed. We will probably need to refer to the source object of the copy with the built-in .oncopy_src, which returns a key to the source object.

Let’s write the beginnings of a coordinate class that uses Stata variables to store vectors of coordinates.

```bash
begin varcoordinate.class
version 15.0
class varcoordinate {
    classwide:
        n = 0
    instancespecific:
        string x
        string y
}
program .new
    .nextnames
    if "'0'" != "" {
        .set '0'
    }
end
program .set
    args x y
    replace '.x' = 'x'
    replace '.y' = 'y'
end
program .nextnames
    .n = '.n' + 1
    .x = "__varcorrd_vname_'.n'"
    .n = '.n' + 1
    .y = "__varcorrd_vname_'.n'"
    generate '.x' = .
    generate '.y' = .
end
program .oncopy
    .nextnames
    .set '.oncopy_src'.x ' .oncopy_src'.y
end
```

This class is more complicated than what we have seen before. We are going to use our own unique variable names to store the \(x\)- and \(y\)-coordinate variables. To ensure that we do not try to reuse the same name, we number these variables by using the classwide counting variable \(n\). Every
time a new instance is created, unique \( x \)- and \( y \)-coordinate variables are created and filled in with missing. This work is done by .nextnames.

The .set looks similar to the one from .varcoordinates except that now we are holding variable names in ‘.x’ and ‘.y’, and we use replace to store the values from the specified variables into our coordinate variables.

The .oncopy member function creates unique names to hold the variables, using .nextnames, and then copies the contents of the coordinate variables from the source object, using .set.

Now, when we type

\[
\text{.coordcopy = .coord}
\]

the \( x \)- and \( y \)-coordinate variables in .coordcopy will be different variables from those in .coord with copies of their values.

The varcoordinate class does not yet do anything interesting, and other than the example in the following section, we will not develop it further.

### 4.9 Advanced cleanup, destructors

We rarely need to concern ourselves with objects being removed when they are deleted or replaced.

When we type

\[
\text{.a = .classname.new}
\]

\[
\text{.b = .classname.new}
\]

\[
\text{.a = .b}
\]

the last command causes the original object, .a, to be destroyed and replaces it with .b. The class system handles this task, which is usually all we want done. An exception is objects that are holding onto items outside the class system, such as the coordinate variables in our destructor class.

When we need to perform actions before the system deletes an object, we write a .destructor member program in the class file. The .destructor for our varcoordinate class is particularly simple; it drops the coordinate variables.

```
begin varcoordinate.class -- destructor

program .destructor
    capture drop '.x'
    capture drop '.y'
end

end varcoordinate.class -- destructor
```

### 5. Inheritance

One class definition can inherit from other class definitions. This is done by including the inherit(classnamelist) option:

```
version 15.0
class newclassname {
    ...
}, inherit(classnamelist)
program ...
    ...
end
...
```

end newclassname.class
newclassname inherits the member variables and member programs from classnamelist. In general, classnamelist contains one class name. When classnamelist contains more than one class name, that is called multiple inheritance.

To be precise, newclassname inherits all the member variables from the classes specified except those that are explicitly defined in newclassname, in which case the definition provided in newclassname.class takes precedence. It is considered bad style to name member variables that conflict.

For multiple inheritance, it is possible that, although a member variable is not defined in newclassname, it is defined in more than one of the “parents” (classnamelist). Then it will be the definition in the rightmost parent that is operative. This too is to be avoided, because it almost always results in programs’ breaking.

newclassname also inherits all the member programs from the classes specified. Here name conflicts are not considered bad style, and in fact, redefinition of member programs is one of the primary reasons to use inheritance.

newclassname inherits all the programs from classnamelist—even those with names in common—and a way is provided to specify which of the programs you wish to run. For single inheritance, if member program .zifl is defined in both classes, then .zifl is taken as the instruction to run .zifl as defined in newclassname, and .Super.zifl is taken as the instruction to run .zifl as defined in the parent.

For multiple inheritance, .zifl is taken as the instruction to run .zifl as defined in newclassname, and .Super(classname).zifl is taken as the instruction to run .zifl as defined in the parent.

A good reason to use inheritance is to “steal” a class and to modify it to suit your purposes. Pretend that you have alreadyexists.class and from that you want to make alternative.class, something that is much like alreadyexists.class—so much like it that it could be used wherever alreadyexists.class is used—but it does one thing a little differently. Perhaps you are writing a graphics system, and alreadyexists.class defines everything about the little circles used to mark points on a graph, and now you want to create alternate.class that does the same, but this time for solid circles. Hence, there is only one member program of alreadyexists.class that you want to change: how to draw the symbol.

In any case, we will assume that alternative.class is to be identical to alreadyexists.class, except that it has changed or improved member function .zifl. In such a circumstance, it would not be uncommon to create

```plaintext
begin alternative.class

version 15.0
class alternative {
}
}, inherit(alreadyexists)
program .zifl

end

```

Moreover, in writing .zifl, you might well call .Super.zifl so that the old .zifl performed its tasks, and all you had to do was code what was extra (filling in the circles, say). In the example above, we added no member variables to the class.
Perhaps the new `.zifl` needs a new member variable—a `double`—and let’s call it `.sizeofresult`. Then we might code

```
version 15.0
class alternative {
    double sizeofresult
}, inherit(alreadyexists)
program .zifl
    ...
end
```

Now let’s consider initialization of the new variable, `.sizeofresult`. Perhaps having it initialized as missing is adequate. Then our code above is adequate. Suppose that we want to initialize it to 5. Then we could include an initializer statement. Perhaps we need something more complicated that must be handled in a `.new`. In this final case, we must call the inherited classes’ `.new` programs by using the `.Super` modifier:

```
version 15.0
class alternative {
    double sizeofresult
}, inherit(alreadyexists)
program .new
    ...
    .Super.new ...
end
program .zifl
    ...
end
```

### 6. Member programs’ return values

Member programs may optionally return “values”, and those can be `doubles`, `strings`, `arrays`, or class instances. These return values can be used in assignment, and thus you can code

```
.len = .li.length
.coord3 = .li.midpoint
```

Just because a member program returns something, it does not mean it has to be consumed. The programs `.li.length` and `.li.midpoint` can still be executed directly,

```
.li.length
.li.midpoint
```

and then the return value is ignored. (`.midpoint` and `.length` are member programs that we included in `line.class`. `.length` returns a double, and `.midpoint` returns a coordinate.)

You cause member programs to return values by using the `class exit` command; see `[P] class exit`.

Do not confuse returned values with return codes, which all Stata programs set, even member programs. Member programs exit when they execute.
Any of the preceding are valid ways of exiting a member program, although the last is perhaps best avoided. `class exit` without arguments has the same effect as `exit` without arguments; it does not matter which you code.

If a member program returns nothing, the result is as if it returned string containing "" (nothing).

Member programs may also return values in r(), e(), and s(), just like regular programs. Using `class exit` to return a class result does not prevent member programs from also being r-class, e-class, or s-class.

### 7. Assignment

Consider `.coord` defined

```plaintext
  .coord = .coordinate.new
```

That is an example of assignment. A new instance of class `coordinate` is created and assigned to `.coord`. In the same way,

```plaintext
  .coord2 = .coord
```

is another example of assignment. A copy of `.coord` is made and assigned to `.coord2`.

Assignment is not allowed just with top-level names. The following are also valid examples of assignment:

```plaintext
  .coord.x = 2
  .li.c0 = .coord
  .li.c0.x = 2+2
  .todo.name = "Jane Smith"
  .todo.n = 2
  .todo.list[1] = "Turn in report"
  .todo.list[2] = .li.c0
```

In each case, what appears on the right is evaluated, and a copy is put into the specified place. Assignment based on the returned value of a program is also allowed, so the following are also valid:

```plaintext
  .coord.x = .li.length
  .li.c0 = .li.midpoint
```

`.length` and `.midpoint` are member programs of `line.class`, and `.li` is an instance of `line`. In the first example, `.li.length` returns a double, and that double is assigned to `.coord.x`. In the second example, `.li.midpoint` returns a `coordinate`, and that `coordinate` is assigned to `.li.c0`.

Also allowed would be

```plaintext
  .todo.list[3] = .color.cvalue, color(green)
  .todo.list = {"Turn in report", .li.c0, [.color.cvalue, color(green)]}
```
In both examples, the result of running `.color.cvalue, color(green)` is assigned to the third array element of `.todo.list`.

### 7.1 Type matching

All the examples above are valid because either a new identifier is being created or the identifier previously existed and was of the same type as the identifier being assigned.

For example, the following would be invalid:

```
.todothing = 2  // valid so far...
.todothing = "new"  // ... invalid
```

The first line is valid because `.todothing` did not previously exist. After the first assignment, however, `.todothing` did exist and was of type `double`. That caused the second assignment to be invalid, the error being “type mismatch”; r(109).

The following are also invalid:

```
.coord.x = .li.midpoint
.li.c0 = .li.length
```

They are invalid because `.li.midpoint` returns a `coordinate`, and `.coord.x` is a `double`, and because `.li.length` returns a `double`, and `.li.c0` is a `coordinate`.

### 7.2 Arrays and array elements

The statements

```
.todo.list[1] = "Turn in report"
.todo.list[2] = .li.c0
.todo.list[3] = .color.cvalue, color(green)
```

and

```
.todo.list = {"Turn in report", .li.c0, [.color.cvalue, color(green)]}
```

do not have the same effect. The first set of statements reassigns elements 1, 2, and 3 and leaves any other defined elements unchanged. The second statement replaces the entire array with an array that has only elements 1, 2, and 3 defined.

After an element has been assigned, it may be unassigned (cleared) using `.Arrdropel`. For example, to unassign `.todo.list[1]`, you would type

```
.todo.list[1].Arrdropel
```

Clearing an element does not affect the other elements of the array. In the above example, `.todo.list[2]` and `.todo.list[3]` continue to exist.

New and existing elements may be assigned and reassigned freely, except that if an array element already exists, it may be reassigned only to something of the same type.

```
```

would be allowed, but

```
.todo.list[2] = "Clear the coordinate"
```
would not be allowed because `.todo.list[2]` is a coordinate and "Clear the coordinate" is a string. If you wish to reassign an array element to a different type, you first drop the existing array element and then assign it.

```plaintext
.todo.list[2].Arrdropel
.todo.list[2] = "Clear the coordinate"
```

### 7.3 lvalues and rvalues

Notwithstanding everything that has been said, the syntax for assignment is

```plaintext
lvalue = rvalue
```

`lvalue` stands for what may appear to the left of the equal sign, and `rvalue` stands for what may appear to the right.

The syntax for specifying an `lvalue` is

```plaintext
.id [.id [...]]
```

where `id` is either a `name` or `name[exp]`, the latter being the syntax for specifying an array element, and `exp` must evaluate to a number; if `exp` evaluates to a noninteger number, it is truncated.

Also an `lvalue` must be assignable, meaning that `lvalue` cannot refer to a member program; that is, an `id` element of `lvalue` cannot be a program name. (In an `rvalue`, if a program name is specified, it must be in the last `id`.)

The syntax for specifying an `rvalue` is any of the following:

- "[string]"
- ‘'[string]'"
- `#
- `exp`
- `(exp)`
- `.id[.id [...] [ program_arguments ]]
- `{}`
- `{el[,el[, ... ]]}

The last two syntaxes concern assignment to arrays, and `el` may be any of the following:

- `nothing`
- "[string]"
- ‘'[string]'"
- `#
- `(exp)`
- `.id[.id [...] [ program_arguments ]]
- `[.id[.id [...] [ program_arguments ]]`

Let’s consider each of the syntaxes for an `rvalue` in turn:

- "[string]" and ‘'[string]'"
  - If the `rvalue` begins with a double quote (simple or compound), a `string` containing `string` will be returned. `string` may be long—up to the length of a macro.
If the *rvalue* is a number excluding missing values ., .a, ..., and .z, a *double* equal to the number specified will be returned.

### *exp* and *(exp)*

If the *rvalue* is an expression, the expression will be evaluated and the result returned. A *double* will be returned if the expression returns a numeric result and a *string* will be returned if expression returns a string. Expressions returning matrices are not allowed.

The expression need not be enclosed in parentheses if the expression does not begin with simple or compound double quotes and does not begin with a period followed by nothing or a letter. In the cases just mentioned, the expression must be enclosed in parentheses. All expressions may be enclosed in parentheses.

An implication of the above is that missing value literals must be enclosed in parentheses:

```
lvalue = (.).
```

### `.id[.id[...]][program_arguments]`

If the *rvalue* begins with a period, it is interpreted as an object reference. The object is evaluated and returned. `.id[.id[...]]` may refer to a member variable or a member program.

If `.id[.id[...]]` refers to a member variable, the value of the variable will be returned.

If `.id[.id[...]]` refers to a member program, the program will be executed and the result returned. If the member program returns nothing, a *string* containing "" (nothing) will be returned.

If `.id[.id[...]]` refers to a member program, arguments may be specified following the program name.

### `{}` and `{el[,el[,...]]}

If the *rvalue* begins with an open brace, an *array* will be returned.

If the *rvalue* is `{}`, an empty array will be returned.

If the *rvalue* is `{el[,el[,...]]}`, an array containing the specified elements will be returned.

If an *el* is nothing, the corresponding array element will be left undefined.

If an *el* is "[string]" or "’[string]’", the corresponding array element will be defined as a *string* containing string.

If an *el* is # excluding missing values ., .a, ..., .z, the corresponding array element will be defined as a *double* containing the number specified.

If an *el* is *(exp)*, the expression is evaluated, and the corresponding array element will be defined as a *double* if the expression returns a numeric result or as a *string* if the expression returns a string. Expressions returning matrices are not allowed.

If an *el* is `.id[.id[...]]` or `[.id[.id[...]][program_arguments]]`, the object is evaluated, and the corresponding array element will be defined according to what was returned. If the object is a member program and arguments need to be specified, the *el* must be enclosed in square brackets.

Recursive array definitions are not allowed.

Finally, in 4.3 *Specifying initialization*—where we discussed member variable initialization—what actually appears to the right of the equal sign is an *rvalue*, and everything just said applies. The previous discussion was incomplete.
7.4 Assignment of reference

Consider two different identifiers, \(a.b.c\) and \(d.e\), that are of the same type. For example, perhaps both are doubles or both are coordinates. When you type

\[a.b.c = d.e\]

the result is to copy the values of \(d.e\) into \(a.b.c\). If you type

\[a.b.c.ref = d.e.ref\]

the result is to make \(a.b.c\) and \(d.e\) be the same object. That is, if you were later to change some element of \(d.e\), the corresponding element of \(a.b.c\) would change, and vice versa.

To understand this, think of member values as each being written on an index card. Each instance of a class has its own collection of cards (assuming no classwide variables). When you type

\[a.b.c.ref = d.e.ref\]

the card for \(a.b.c\) is removed and a note is substituted that says to use the card for \(d.e\). Thus both \(a.b.c\) and \(d.e\) become literally the same object.

More than one object can share references. If we were now to code

\[i.ref = a.b.c.ref\]

or

\[i.ref = d.e.ref\]

the result would be the same: \(i\) would also share the already-shared object.

We now have \(a.b.c\), \(d.e\), and \(i\) all being the same object. Say that we want to make \(d.e\) into its own unique object again. We type

\[d.e.ref = \text{anything evaluating to the right type not ending in } ref\]

We could, for instance, type any of the following:

\[d.e.ref = \text{classname.new}\]
\[d.e.ref = j.k\]
\[d.e.ref = d.e\]

All the above will make \(d.e\) unique because what is returned on the right is a copy. The last of the three examples is intriguing because it results in \(d.e\) not changing its values but becoming once again unique.

8. Built-ins

\text{new} and \text{ref} are examples of built-in member programs that are included in every class. There are other built-ins as well.

Built-ins may be used on any object except programs and other built-ins. Let \(B\) refer to a built-in. Then

- If \(a.b.myprog\) refers to a program, \(a.b.myprog.B\) is an error (and, in fact, \(a.b.myprog.anything\) is also an error).
- \(a.b.B.anything\) is an error.
Built-ins come in two forms: built-in functions and built-in modifiers. Built-in functions return information about the class or class instance on which they operate but do not modify the class or class instance. Built-in modifiers might return something—in general they do not—but they modify (change) the class or class instance.

Except for `.new` (and that was covered in 4.4 Specifying initialization 2, `.new`), built-ins may not be redefined.

### 8.1 Built-in functions

In the documentation below, `object` refers to the context of the built-in function. For example, if `.a.b.F` is how the built-in function `.F` was invoked, then `.a.b` is the object on which it operates.

The built-in functions are

- `.new` returns a new instance of `object`. `.new` may be used whether the `object` is a class name or an instance, although it is most usually used with a class name. For example, if `coordinate` is a class, `.coordinate.new` returns a new instance of `coordinate`.

  If `.new` is used with an instance, a new instance of the class of the object is returned; the current instance is not modified. For example, if `.a.b` is an instance of `coordinate`, then `.a.b.new` does exactly what `.coordinate.new` would do; `.a.b` is not modified in any way.

  If you define your own `.new` program, it is run after the built-in `.new` is run.

- `.copy` returns a new instance—a copy—of `object`, which must be an instance. `.copy` returns a new object that is a copy of the original.

- `.ref` returns a reference to the object. See 7.4 Assignment of reference.

- `.objtype` returns a string indicating the type of `object`. Returned is one of "double", "string", "array", or "classname".

- `.isa` returns a string indicating the category of `object`. Returned is one of "double", "string", "array", "class", or "classtype". "classtype" is returned when `object` is a class definition; "class" is returned when the object is an instance of a class (sic).

- `.classname` returns a string indicating the name of the class. Returned is "classname" or, if `object` is of type double, string, or array, returned is "".

- `.isofclass classname` returns a double. Returns 1 if `object` is of class type `classname` and 0 otherwise. To be of a class type, `object` must be an instance of `classname`, inherited from the class `classname`, or inherited from a class that inherits anywhere along its inheritance path from `classname`.

- `.objkey` returns a string that can be used to reference an object outside the implied context. See 12.1 Keys.

- `.uname` returns a string that can be used as a name throughout Stata that corresponds to the object. See 12.2 Unames.
.ref_n
returns a double. Returned is the total number of identifiers sharing object. Returned is 1 if the object is unshared. See 7.4 Assignment of reference.

.arrnels
returns a double. .arrnels is for use with arrays; it returns the largest index of the array that has been assigned data. If object is not an array, it returns an error.

.arrindexof "string"
returns a double. .arrindexof is for use with arrays; it searches the array for the first element equal to string and returns the index of that element. If string is not found, .arrindexof returns 0. If object is not an array, it returns an error.

.classmv
returns an array containing the .refs of each classwide member variable in object. See 12.3 Arrays of member variables.

.instancemv
returns an array containing the .refs of each instance-specific member variable in object. See 12.3 Arrays of member variables.

.dynamicmv
returns an array containing the .refs of each dynamically allocated member variable in object. See 12.3 Arrays of member variables.

.superclass
returns an array containing the .refs of each of the classes from which the specified object inherited. See 12.3 Arrays of member variables.

8.2 Built-in modifiers
Modifiers are built-ins that change the object to which they are applied. All built-in modifiers have names beginning with a capital letter. The built-in modifiers are

.Declare declarator
returns nothing. .Declare may be used only when object is a class instance. .Declare adds the specified new member variable to the class instance. See 4.7 Adding dynamically.

.Arrdropel #
returns nothing. .Arrdropel may be used only with array elements. .Arrdropel drops the specified array element, making it as if it was never defined. .arrnels is, of course, updated. See 7.2 Arrays and array elements.

.Arrdropall
returns nothing. .Arrdropall may be used only with arrays. .Arrdropall drops all elements of an array. .Arrdropall is the same as .arrayname = {}. If object is not an array, .Arrdropall returns an error.

.Arrpop
returns nothing. .Arrpop may be used only with arrays. .Arrpop finds the top element of an array (largest index) and removes it from the array. To access the top element before popping, use .arrayname[‘.arrayname.arrnels’]. If object is not an array, .Arrpop returns an error.

.Arrpush "string"
returns nothing. .Arrpush may be used only with arrays. .Arrpush pushes string onto the end of the array, where end is defined as .arrnels+1. If object is not an array, .Arrpush returns an error.
9. Prefix operators

There are three prefix operators:

- `.Global`
- `.Local`
- `.Super`

Prefix operators determine how object names such as `.a`, `.a.b`, `.a.b.c`, ... are resolved.

Consider a program invoked by typing `.alpha.myprog`. In program `.myprog`, any lines such as

```
.a = .b
```

are interpreted according to the implied context, if that is possible. `.a` is interpreted to mean `.alpha.a` if `.a` exists in `.alpha`; otherwise, it is taken to mean `.a` in the global context, meaning that it is taken to mean just `.a`. Similarly, `.b` is taken to mean `.alpha.b` if `.b` exists in `.alpha`; otherwise, it is taken to mean `.b`.

What if `.myprog` wants `.a` to be interpreted in the global context even if `.a` exists in `.alpha`? Then the code would read

```
.Global.a = .b
```

If instead `.myprog` wanted `.b` to be interpreted in the global context (and `.a` to be interpreted in the implied context), the code would read

```
.a = .Global.b
```

Obviously, if the program wanted both to be interpreted in the global context, the code would read

```
.Global.a = .Global.b
```

`.Local` is the reverse of `.Global`: it ensures that the object reference is interpreted in the implied context. `.Local` is rarely specified because the local context is searched first, but if there is a circumstance where you wish to be certain that the object is not found in the global context, you may specify its reference preceded by `.Local`. Understand, however, that if the object is not found, an error will result, so you would need to precede commands containing such references with `capture`; see [P] capture.

In fact, if it is used at all, `.Local` is nearly always used in a macro-substitution context—something discussed in the next section—where errors are suppressed and where nothing is substituted when errors occur. Thus in advanced code, if you were trying to determine whether member variable `.addedvar` exists in the local context, you could code

```plaintext
if "'Local.addedvar.objtype'" == "" {
    /* it does not exist */
} else {
    /* it does */
}
```

The `.Super` prefix is used only in front of program names and concerns inheritance when one program occults another. This was discussed in 5. Inheritance.
10. Using object values

We have discussed definition and assignment of objects, but we have not yet discussed how you
might use class objects in a program. How do you refer to their values in a program? How do you
find out what a value is, skip some code if the value is one thing, and loop if it is another?

The most common way to refer to objects (and the returned results of member programs) is through
macro substitution; for example,

```plaintext
local x = '.li.c0.x'
local clr "'.color.cvalue, color(green)''
scalar len = '.coord.length'
forvalues i=1(1).todo.n' {
    Mysub "todo.list[\'i\'][\'n\']"
}
```

When a class object is quoted, its printable form is substituted. This is defined as

<table>
<thead>
<tr>
<th>Object type</th>
<th>Printable form</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>contents of the string</td>
</tr>
<tr>
<td>double</td>
<td>number printed using %18.0g, spaces stripped</td>
</tr>
<tr>
<td>array</td>
<td>nothing</td>
</tr>
<tr>
<td>classname</td>
<td>nothing or, if member program .macroexpand is defined, then string or double returned</td>
</tr>
</tbody>
</table>

Any object may be quoted, including programs. If the program takes arguments, they are included
inside the quotes:

```plaintext
scalar len = '.coord.length'
local clr "'.color.cvalue, color(green)''
```

If the quoted reference results in an error, the error message is suppressed, and nothing is substituted.

Similarly, if a class instance is quoted—or a program returning a class instance is quoted—nothing
is substituted. That is, nothing is substituted, assuming that the member program .macroexpand has
not been defined for the class, as is usually the case. If .macroexpand has been defined, however, it
is executed, and what macroexpand returns—which may be a string or a double—is substituted.

For example, say that we wanted to make all objects of type coordinate substitute (#, #) when
they were quoted. In the class definition for coordinate, we could define .macroexpand,
and now coordinates will be substituted. Say that .mycoord is a coordinate currently set to (2,3). If we did not include .macroexpand in the coordinate.class file, typing

```plaintext
...‘.mycoord’...
```

would not be an error but would merely result in

```
......
```

Having defined .macroexpand, it will result in

```
...(2,3)...
```

A .macroexpand member function is intended as a utility for returning the printable form of a class instance and nothing more. In fact, the class system prevents unintended corruption of class-member variables by making a copy, returning the printable form, and then destroying the copy. These steps ensure that implicitly calling .macroexpand has no side effects on the class instance.

11. Object destruction

To create an instance of a class, you type

```plaintext
.name = .classname.new [arguments]
```

To destroy the resulting object and thus release the memory associated with it, you type

```plaintext
classutil drop .name
```

(See [P] classutil for more information on the classutil command.) You can drop only top-level instances. Objects deeper than that are dropped when the higher-level object containing them is dropped, and classes are automatically dropped when the last instance of the class is dropped.

Also any top-level object named with a name obtained from tempname—see [P] macro—is automatically dropped when the program concludes. Even so, tempname objects may be returned by class exit. The following is valid:

```plaintext
program .tension
...
tempname a b
.'a' = .bubble.new
.'b' = .bubble.new
...
class exit .‘a’
end
```
The program creates two new class instances of bubbles in the global context, both with temporary names. We can be assured that ‘a’ and ‘b’ are global because the names ‘a’ and ‘b’ were obtained from tempname and therefore cannot already exist in whatever context in which .tension runs. Therefore, when the program ends, ‘a’ and ‘b’ will be automatically dropped. Even so, .tension can return ‘a’. It can do that because, at the time class exit is executed, the program has not yet concluded and ‘a’ still exists. You can even code

```
program .tension
    ...
    tempname a b
    ‘a’ = .bubble.new
    ‘b’ = .bubble.new
    ...
    class exit .‘a’.ref
end
```

and that also will return .a and, in fact, will be faster because no extra copy will be made. This form is recommended when returning an object stored in a temporary name. Do not, however, add .refs on the end of “real” (nontemporary) objects being returned because then you would be returning not just the same values as in the real object but the object itself.

You can clear the entire class system by typing discard; see [P] discard. There is no classutil drop _all command: Stata’s graphics system also uses the class system, and dropping all the class definitions and instances would cause graph difficulty. discard also clears all open graphs, so the disappearance of class definitions and instances causes graph no difficulty.

During the development of class-based systems, you should type discard whenever you make a change to any part of the system, no matter how minor or how certain you are that no instances of the definition modified yet exist.

### 12. Advanced topics

#### 12.1 Keys

The .objkey built-in function returns a string called a key that can be used to reference the object as an rvalue but not as an lvalue. This would typically be used in

```
local k = ‘.a.b.objkey’
```

or

```
.c.k = .a.b.objkey
```

where .c.k is a string. Thus the keys stored could be then used as follows:

```
.d = ‘k’.x    meaning to assign .a.b.x to .d
.d = ‘c.k’.x    (same)
local z = ‘.k’.x    meaning to put value of .a.b.x in ‘z’
local z = ‘.c.k’.x    (same)
```

It does not matter if the key is stored in a macro or a string member variable—it can be used equally well—and you always use the key by macro quoting.

A key is a special string that stands for the object. Why not, you wonder, simply type .a.b rather than ‘.c.k’ or ‘k’? The answer has to do with implied context.
Pretend that .myvar.bin.myprogram runs .myprogram. Obviously, it runs .myprogram in the context .myvar.bin. Thus .myprogram can include lines such as

\[ x = 5 \]

and that is understood to mean that .myvar.bin.x is to be set to 5. .myprogram, however, might also include a line that reads

```
.Global.utility.setup `.x.objkey'
```

Here .myprogram is calling a utility that runs in a different context (namely, .utility), but myprogram needs to pass .x—of whatever type it might be—to the utility as an argument. Perhaps .x is a coordinate, and .utility.setup expects to receive the identifier of a coordinate as its argument. .myprogram, however, does not know that .myvar.bin.x is the full name of .x, which is what .utility.setup will need, so .myprogram passes `.x.objkey’. Program .utility.setup can use what it receives as its argument just as if it contained .myvar.bin.x, except that .utility.setup cannot use that received reference on the left-hand side of an assignment.

If myprogram needed to pass to .utility.setup a reference to the entire implied context (.myvar.bin), the line would read

```
.Global.utility.setup `.objkey'
```

because .objkey by itself means to return the key of the implied context.

### 12.2 Unames

The built-in function .uname returns a name that can be used throughout Stata that uniquely corresponds to the object. The mapping is one way. Unames can be obtained for objects, but the original object’s name cannot be obtained from the uname.

Pretend that you have object .a.b.c, and you wish to obtain a name you can associate with that object because you want to create a variable in the current dataset, or a value label, or whatever else, to go along with the object. Later, you want to be able to reobtain that name from the object’s name. .a.b.c.uname will provide that name. The name will be ugly, but it will be unique. The name is not temporary: you must drop whatever you create with the name later.

Unames are, in fact, based on the object’s .ref. That is, consider two objects, .a.b.c and .d.e, and pretend that they refer to the same data; that is, you have previously executed

```
.a.b.c.ref = .d.e.ref
```

or

```
.d.e.ref = .a.b.c.ref
```

Then .a.b.c.uname will equal .d.e.uname. The names returned are unique to the data being recorded, not the identifiers used to arrive to the data.

As an example of use, within Stata’s graphics system sersets are used to hold the data behind a graph; see [P] serset. An overall graph might consist of several graphs. In the object nesting for a graph, each individual graph has its own object holding a serset for its use. The individual objects, however, are shared when the same serset will work for two or more graphs, so that the same data are not recorded again and again. That is accomplished by simply setting their .refs equal. Much later in the graphics code, when that code is writing a graph out to disk for saving, it needs to figure out which sersets need to be saved, and it does not wish to write shared sersets out multiple times. Stata finds out what sersets are shared by looking at their unames and, in fact, uses the unames to help it keep track of which sersets go with which graph.
12.3 Arrays of member variables

Note: The following functions are of little use in class programming. They are of use to those writing utilities to describe the contents of the class system, such as the features documented in \[P\] classutil.

The built-in functions .classmv, .instancemv, and .dynamicmv each return an array containing the .refs of each classwide, instance-specific, and dynamically declared member variables. These array elements may be used as either \textit{lvalues} or \textit{rvalues}.

.superclass also returns an array containing .refs, these being references to the classes from which the current object inherited. These array elements may be used as \textit{rvalues} but should not be used as \textit{lvalues} because they refer to underlying class definitions themselves.

.classmv, .instancemv, .dynamicmv, and .superclass, although documented as built-in functions, are not really functions, but instead are built-in member variables. This means that, unlike built-in functions, their references may be followed by other built-in functions, and it is not an error to type, for instance,

\[
... \_.\text{li}.\text{instancemv}.\text{arrnels} ... 
\]

and it would be odd (but allowed) to type

\[
\text{myarray} = \_.\text{li}.\text{instancemv} 
\]

It would be odd simply because there is no reason to copy them because you can use them in place.

Each of the above member functions are a little sloppy in that they return nothing (produce an error) if there are no classwide, instance-specific, and dynamically declared member variables, or no inherited classes. This sloppiness has to do with system efficiency, and the proper way to work around the sloppiness is to obtain the number of elements in each array as 0'.classmv.arrnels', 0'.instancemv.arrnels', 0'.dynamicmv.arrnels', and 0'.superclass.arrnels'. If an array does not exist, then nothing will be substituted, and you will still be left with the result 0.

For example, assume that .my.c is of type coordinate2, defined as

\begin{verbatim}
version 15.0
class coordinate2 {
    classwide:
        double x_origin = 0
        double y_origin = 0
    instancespecific:
        double x = 0
        double y = 0
}
\end{verbatim}

Then

<table>
<thead>
<tr>
<th>referring to ...</th>
<th>is equivalent to referring to ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>.my.c.classmv[1]</td>
<td>.my.c.c.x_origin</td>
</tr>
<tr>
<td>.my.c.classmv[2]</td>
<td>.my.c.c.y_origin</td>
</tr>
<tr>
<td>.my.cinstancemv[1]</td>
<td>.my.c.c.x</td>
</tr>
<tr>
<td>.my.cinstancemv[2]</td>
<td>.my.c.c.y</td>
</tr>
</tbody>
</table>
If any member variables were added dynamically using .Dynamic, they could equally well be accessed via .my.c.dynamicmv[] or their names. Either of the above could be used on the left or right of an assignment.

If coordinate2.class inherited from another class (it does not), referring to .coordinate2.superclass[1] would be equivalent to referring to the inherited class; .coordinate2.superclass[1].new, for instance, would be allowed.

These “functions” are mainly of interest to those writing utilities to act on class instances as a general structure.

Appendix A. Finding, loading, and clearing class definitions

The definition for class xyz is located in file xyz.class.

Stata looks for xyz.class along the ado-path in the same way that it looks for ado-files; see [U] 17.5 Where does Stata look for ado-files? and see [P] sysdir.

Class definitions are loaded automatically, as they are needed, and are cleared from memory as they fall into disuse.

When you type discard, all class definitions and all existing instances of classes are dropped; see [P] discard.

Appendix B. Jargon

built-in: a member program that is automatically defined, such as .new. A built-in function is a member program that returns a result without changing the object on which it was run. A built-in modifier is a member program that changes the object on which it was run and might return a result as well.

class: a name for which there is a class definition. If we say that coordinate is a class, then coordinate.class is the name of the file that contains its definition.

class instance: a “variable”; a specific, named copy (instance) of a class with its member values filled in; an identifier that is defined to be of type classname.

classwide variable: a member variable that is shared by all instances of a class. Its alternative is an instance-specific variable.

inheritance: the ability to define a class in terms of one (single inheritance) or more (multiple inheritance) existing classes. The existing class is typically called the base or super class, and by default, the new class inherits all the member variables and member programs of the base class.

identifier: the name by which an object is identified, such as .mybox or .mybox.x.

implied context: the instance on which a member program is run. For example, in .a.b.myprog, .a.b is the implied context, and any references to, say, .x within the program, are first assumed to, in fact, be references to .a.b.x.

instance: a class instance.

instance-specific variable: a member variable that is unique to each instance of a class; each instance has its own copy of the member variable. Its alternative is a classwide variable.

lvalue: an identifier that may appear to the left of the = assignment operator.

member program: a program that is a member of a class or of an instance.

member variable: a variable that is a member of a class or of an instance.
object: a class or an instance; this is usually a synonym for an instance, but in formal syntax definitions, if something is said to be allowed to be used with an object, that means it may be used with a class or with an instance.

polymorphism: when a system allows the same program name to invoke different programs according to the class of the object. For example, .draw might invoke one program when used on a star object, .mystar.draw, and a different program when used on a box object, .mybox.draw.

reference: most often the word is used according to its English-language definition, but a .ref reference can be used to obtain the data associated with an object. If two identifiers have the same reference, then they are the same object.

return value: what an object returns, which might be of type double, string, array, or classname. Generally, return value is used in discussions of member programs, but all objects have a return value; they typically return a copy of themselves.

rvalue: an identifier that may appear to the right of the = assignment operator.

scope: how it is determined to what object an identifier references. .a.b might be interpreted in the global context and literally mean .a.b, or it might be interpreted in an implied context to mean .impliedcontext.a.b.

shared object: an object to which two or more different identifiers refer.

type: the type of a member variable or of a return value, which is double, string, array, or classname.

Appendix C. Syntax diagrams

Appendix C.1 Class declaration

```
class [newclassname] {  
   [classwide:]  
      [type mvname [= rvalue]]  
      [mvname = rvalue]  
   [instancespecific:]  
      [type mvname [= rvalue]]  
      [mvname = rvalue ]  
   [\ldots]  
} [, inherit(classnamelist)]  
```

where

- \( mvname \) stands for member variable name;
- \( rvalue \) is defined in Appendix C.2 Assignment; and
- \( type \) is \{classname | double | string | array \}.  

The .Declare built-in may be used to add a member variable to an existing class instance,

\[ \text{id[.id[...]].Declare type newmvname [ = rvalue] } \]
\[ \text{id[.id[...]].Declare newmvname = rvalue} \]

where \text{id} is \{\text{name} | \text{name[exp]}\}, the latter being how you refer to an array element; \text{exp} must evaluate to a number. If \text{exp} evaluates to a noninteger number, it is truncated.

**Appendix C.2 Assignment**

\[ lvalue = rvalue \]
\[ lvalue\.ref = lvalue\.ref (sic) \]
\[ lvalue\.ref = rvalue \]

where

\text{lvalue} is \text{id[.id[...]]}

\text{rvalue} is

"[string]"
'"[string]",
#
\text{exp}
(exp)
\text{id[.id[...]]}

[ .id[.id[...]].pgmname [pgm_arguments] ]
[ .id[.id[...]].Super[ (classname) ] .pgmname [pgm_arguments] ]
{}
{el [ ,el [ ,... ]]}

When \text{exp} evaluates to a string, the result will contain at most 2045 characters and will be terminated early if it contains a binary 0.

The last two syntaxes concern assignment to arrays; \text{el} may be

\text{nothing}
"[string]"
'"[string]",
#
\text{(exp)}
\text{id[.id[...]]}

[ .id[.id[...]].pgmname ]
[ .pgmname [pgm_arguments] ]

\text{id} is \{\text{name} | \text{name[exp]}\}, the latter being how you refer to an array element; \text{exp} must evaluate to a number. If \text{exp} evaluates to a noninteger number, it is truncated.
Appendix C.3 Macro substitution

Values of member variables or values returned by member programs can be substituted in any Stata command line in any context using macro quoting. The syntax is

\[ \ldots 'id[id[\ldots]]' \ldots \]

\[ \ldots 'id[id[\ldots]].pgmname' \ldots \]

\[ \ldots 'id[id[\ldots]].pgmname pgm_arguments' \ldots \]

\[ \ldots 'id[id[\ldots]].Super(classname).pgmname' \ldots \]

\[ \ldots 'id[id[\ldots]].Super(classname).pgmname pgm_arguments' \ldots \]

Nested substitutions are allowed. For example,

\[ \ldots 'tmpname.x' \ldots \]

\[ \ldots 'ref' \ldots \]

In the above, perhaps local `tmpname` was obtained from `tempname` (see [P] macro), and perhaps local `ref` contains `'myobj.cvalue'`.

When a class object is quoted, its printable form is substituted. This is defined as

<table>
<thead>
<tr>
<th>Object type</th>
<th>Printable form</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>contents of the string</td>
</tr>
<tr>
<td>double</td>
<td>number printed using %18.0g, spaces stripped</td>
</tr>
<tr>
<td>array</td>
<td>nothing</td>
</tr>
<tr>
<td>classname</td>
<td>nothing or, if member program .macroexpand is defined, then string or double returned</td>
</tr>
</tbody>
</table>

If the quoted reference results in an error, the error message is suppressed and nothing is substituted.

Appendix C.4 Quick summary of built-ins

Built-ins come in two forms: 1) built-in functions—built-ins that return a result but do not change the object on which they are run, and 2) built-in modifiers—built-ins that might return a result but more importantly modify the object on which they are run.
Built-in functions (may be used as *rvalues*)

- `.object.id` creates new instance of `.object`
- `.instance.copy` makes a copy of `.instance`
- `.instance.ref` for use in assignment by reference
- `.object.objtype` returns “double”, “string”, “array”, or “classname”
- `.object.isa` returns “double”, “string”, “array”, “class”, or “classtype”
- `.object.classname` returns “classname” or “”
- `.object.isofclass classname` returns 1 if `.object` is of class type `classname`
- `.object.objkey` returns a string that can be used to refer to an object outside the implied context
- `.object.uname` returns a string that can be used as `name` throughout Stata; `name` corresponds to `.object`'s `.ref`
- `.object.ref_n` returns number (double) of total number of identifiers sharing object
- `.array.arrnels` returns number (double) corresponding to largest index of the array assigned
- `.array.arrindexof "string"` searches array for first element equal to `string` and returns the index (double) of element or returns 0
- `.object.classmv` returns array containing the `.refs` of each classwide member of `.object`
- `.objectinstancemv` returns array containing the `.refs` of each instance-specific member of `.object`
- `.object.dynamcmv` returns array containing the `.refs` of each dynamically added member of `.object`
- `.object.superclass` returns array containing the `.refs` of each of the classes from which `.object` inherited

Built-in modifiers

- `.instance.Declare declarator` returns nothing; adds member variable to instance; see *Appendix C.1 Class declaration*
- `.array[exp].Arrdropel #` returns nothing; drops the specified array element
- `.array.Arrpop` returns nothing; finds the top element and removes it
- `.array.Arrpush "string"` returns nothing; adds string to end of array
Also see

[P] class exit — Exit class-member program and return result
[P] classutil — Class programming utility
[P] sysdir — Query and set system directories
[M-2] class — Object-oriented programming (classes)
[U] 17.5 Where does Stata look for ado-files?
class exit — Exit class-member program and return result

Description
class exit exits a class-member program and optionally returns the specified result.
class exit may be used only from class-member programs; see [P] class.

Syntax
class exit [ rvalue ]

where rvalue is

"[ string ]"
"[ string ]"
#
exp
(exp)
.id[.id[...]] [ program_arguments ]
{
}
{/el[,el[,...]]}

See [P] class for more information on rvalues.

Remarks and examples
Do not confuse returned values with return codes, which all Stata programs set, including member programs. Member programs exit when they execute.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Returned value</th>
<th>Return code</th>
</tr>
</thead>
<tbody>
<tr>
<td>class exit with arguments</td>
<td>as specified</td>
<td>0</td>
</tr>
<tr>
<td>class exit without arguments</td>
<td>nothing</td>
<td>0</td>
</tr>
<tr>
<td>exit without arguments</td>
<td>nothing</td>
<td>0</td>
</tr>
<tr>
<td>exit with arguments</td>
<td>nothing</td>
<td>as specified</td>
</tr>
<tr>
<td>error</td>
<td>nothing</td>
<td>as specified</td>
</tr>
<tr>
<td>command having error</td>
<td>nothing</td>
<td>as appropriate</td>
</tr>
</tbody>
</table>

Any of the preceding are valid ways of exiting a member program, although the last is perhaps best avoided. class exit without arguments has the same effect as exit without arguments; it does not matter which you use.
Examples

```plaintext
class exit sqrt((‘.c0.y1’–‘.c1.y0’)^2 + (‘.c0.y1’–‘.c1.y0’)^2)
class exit "myresult"
class exit (.)
class exit "true"
class exit {‘one’, ‘two’}
class exit .coord
class exit .coord.x
tempname a
...  
class exit .‘a’
```

Warning: Distinguish carefully between “class exit .a” and “class exit (.a)”. The first returns a copy of the instance .a. The second returns a double equal to the extended missing value .a.

[P] class — Class programming
[P] exit — Exit from a program or do-file
[M-2] class — Object-oriented programming (classes)
classutil — Class programming utility

Description

If you have not yet read [P] class, please do so. classutil stands outside the class system and provides utilities for examining and manipulating what it contains.

classutil drop drops the specified top-level class instances from memory. To drop all class objects, type discard; see [P] discard.

classutil describe displays a description of an object.

classutil dir displays a list of all defined objects.

classutil cdir displays a directory of all classes available.

classutil which lists which .class file corresponds to the class specified.

Syntax

Drop class instances from memory

```
classutil drop instance [instance [...]]
```

Describe object

```
classutil describe object [, recurse newok]
```

List all defined objects

```
classutil dir [pattern] [, all detail]
```

Display directory of available classes

```
classutil cdir [pattern]
```

List .class file corresponding to classname

```
classutil which classname [, all]
```

where

- `object`, `instance`, and `classname` may be specified with or without a leading period.
- `instance` and `object` are as defined in [P] class: `object` is an `instance` or a `classname`.
- `pattern` is as allowed with the `strmatch()` function: `*` means that 0 or more characters go here, and `?` means that exactly one character goes here.

Command `cutil` is a synonym for `classutil`.  

Options for classutil describe

recurse specifies that classutil describe be repeated on any class instances or definitions that occur within the specified object. Consider the case where you type classutil describe .myobj, and myobj contains myobj.c0, which is a coordinate. Without the recurse option, you will be informed that myobj.c0 is a coordinate, and classutil describe will stop right there.

With the recurse option, you will be informed that myobj.c0 is a coordinate, and then classutil describe will proceed to describe .myobj.c0, just as if you had typed "classutil describe .myobj.c0". If .myobj.c0 itself includes classes or class instances, they too will be described.

newok is relevant only when describing a class, although it is allowed—and ignored—at other times. newok allows classes to be described even when no instances of the class exist.

When asked to describe a class, Stata needs to access information about that class, and Stata knows the details about a class only when one or more instances of the class exist. If there are no instances, Stata is stuck—it does not know anything other than a class of that name exists. newok specifies that, in such a circumstance, Stata may temporarily create an instance of the class by using .new. If Stata is not allowed to do this, then Stata cannot describe the class. The only reason you are being asked to specify newok is that in some complicated systems, running .new can have side effects, although in most complicated and well-written systems, that will not be the case.

Options for classutil dir

all specifies that class definitions (classes) be listed, as well as top-level instances.

detail specifies that a more detailed description of each of the top-level objects be provided. The default is simply to list the names of the objects in tabular form.

Option for classutil which

all specifies that classutil which list all files along the search path with the specified name, not just the first one (the one Stata will use).

Remarks and examples

Remarks are presented under the following headings:

- classutil drop
- classutil describe
- classutil dir
- classutil cdir
- classutil which

classutil drop

classutil drop may be used only with top-level instances, meaning objects other than classes having names with no dots other than the leading dot. If .mycoord is of type coordinate (or of type double), it would be allowed to drop .mycoord but not coordinate (or double). Thus each of the following would be valid, assuming that each is not a class definition:
. classutil drop .this
. classutil drop .mycolor
. classutil drop .this .mycolor

The following would be invalid, assuming that coordinate is a class:

. classutil drop coordinate

There is no need to drop classes because they are automatically dropped when the last instance of
them is dropped.

The following would not be allowed because they are not top-level objects:

. classutil drop .this.that
. classutil drop .mycolor.color.rgb[1]

Second-, third-, and higher-level objects are dropped when the top-level objects containing them are
dropped.

In all the examples above, we have shown objects identified with leading periods, as is typical.
The period may, however, be omitted.

. classutil drop this mycolor

Technical note

Stata’s graphics are implemented using classes. If you have a graph displayed, be careful not to
drop objects that are not yours. If you drop a system object, Stata will not crash, but graph may
produce some strange error messages. If you are starting a development project, it is best to discard
(see [P] discard) before starting—that will eliminate all objects and clear any graphs. This way, the
only objects defined will be the objects you have created.

classutil describe

classutil describe presents a description of the object specified. The object may be a class
or an instance and may be of any depth. The following are all valid:

. classutil describe coordinate
. classutil describe .this
. classutil describe .color.rgb
. classutil describe .color.rgb[1]

The object may be specified with or without a leading period; it makes no difference.

Also see above the descriptions of the recurse and newok options. The following would also be
allowed:

. classutil describe coordinate, newok
. classutil describe line, recurse
. classutil describe line, recurse newok
classutil dir

classutil dir lists all top-level instances currently defined. Note the emphasis on instances: class definitions (classes) are not listed. classutil dir, all will list all objects, including the class definitions.

If the detail option is specified, a more detailed description is presented, but it is still less detailed than that provided by classutil describe.

_pattern_, if specified, is as defined for Stata’s strmatch() function: * means that 0 or more characters go here, and ? means that exactly one character goes here. If _pattern_ is specified, only top-level instances or objects matching the pattern will be listed. Examples include

```plaintext
. classutil dir
. classutil dir, detail
. classutil dir, detail all
. classutil dir c*
. classutil dir *_g, detail
```

classutil cdir

classutil cdir lists the available classes. Without arguments, all classes are listed. If _pattern_ is specified, only classes matching the pattern are listed:

```plaintext
. classutil cdir
. classutil cdir c*
. classutil cdir coord*
. classutil cdir *_g
. classutil cdir color_?_?_*
```

_pattern_ is as defined for Stata’s strmatch() function: * means that 0 or more characters go here, and ? means that exactly one character goes here.

classutil cdir obtains the list by searching for *.class files along the ado-path; see [P] sysdir.

classutil which

classutil which identifies the .class file associated with class classname and displays lines from the file that begin with *!. For example,

```plaintext
. classutil which mycolortype
C:\ado\personal\mycolortype.class
*! version 1.0.1
. classutil which badclass
file "badclass.class" not found
r(611);
```

classutil which searches in the standard way for the .class files, that is, by looking for them along the ado-path; see [P] sysdir.
With the `all` option, `classutil which` lists all files along the search path with the specified name, not just the first one found (the one Stata would use):

```
. classutil which mycolortype, all
C:\ado\personal\mycolortype.class
!*  version 1.0.1
C:\ado\plus\m\mycolortype.class
!*  version 1.0.0
```

*! lines have to do with versioning. * is one of Stata’s comment markers, so *! lines are comment lines. *! is a convention that some programmers use to record version or author information. If there are no *! lines, then only the filename is listed.

### Stored results

- `classutil drop` returns nothing.
- `classutil describe` returns macro `r(type)` containing `double`, `string`, `classname`, or `array` and returns `r(bitype)` containing the same, except that if `r(type)=="classname"`, `r(bitype)` contains `class` or `instance`, depending on whether the object is the definition or an instance of the class.
- `classutil cdir` returns in macro `r(list)` the names of the available classes matching the pattern specified. The names will not be preceded by a period.
- `classutil dir` returns in macro `r(list)` the names of the top-level instances matching the pattern specified as currently defined in memory. The names will be preceded by a period if the corresponding object is an instance and will be unadorned if the corresponding object is a class definition.
- `classutil which` without the `all` option returns in `r(fn)` the name of the file found; the name is not enclosed in quotes. With the `all` option, `classutil which` returns in `r(fn)` the names of all the files found, listed one after the other and each enclosed in quotes.

[P] class — Class programming
Title

comments — Add comments to programs

Description

This entry provides a quick reference for how to specify comments in programs. See [U] 16.1.2 Comments and blank lines in do-files for more details.

Remarks and examples

Comments may be added to programs in three ways:

- begin the line with `*`;
- begin the comment with `//`; or
- place the comment between `/*` and `*/` delimiters.

Here are examples of each:

```plaintext
* a sample analysis job
version 15.0
use census
/* obtain the summary statistics */
tabulate region // there are 4 regions in this dataset
summarize marriage

* a sample analysis job
version 15.0
use /* obtain the summary statistics */ census
tabulate region
// there are 4 regions in this dataset
summarize marriage
```

The comment indicator `*` may be used only at the beginning of a line, but it does have the advantage that it can be used interactively. `*` indicates that the line is to be ignored. The `*` comment indicator may not be used within Mata.

The `//` comment indicator may be used at the beginning or at the end of a line. However, if the `//` indicator is at the end of a line, it must be preceded by one or more blanks. That is, you cannot type the following:

```plaintext
tabulate region// there are 4 regions in this dataset
```

`//` indicates that the rest of the line is to be ignored.

The `/*` and `*/` comment delimiter has the advantage that it may be used in the middle of a line, but it is more cumbersome to type than the other two comment indicators. What appears inside `/*` `*/` is ignored.

64
Technical note

There is a fourth comment indicator, ///, that instructs Stata to view from /// to the end of a line as a comment and to join the next line with the current line. For example,

```
args a /// input parameter for a
b /// input parameter for b
c // input parameter for c
```

is equivalent to

```
args a b c
```

/// is one way to make long lines more readable:

```
replace final_result = ///
   sqrt(first_side^2 + second_side^2) ///
   if type == "rectangle"
```

Another popular method is

```
replace final_result = /*
 */ sqrt(first_side^2 + second_side^2) /*
 */ if type == "rectangle"
```

Like the // comment indicator, the /// indicator must be preceded by one or more blanks.

[P] #delimit — Change delimiter
[U] 16.1.2 Comments and blank lines in do-files
[U] 18.11.2 Comments and long lines in ado-files
confirm — Argument verification

Description

confirm verifies that the arguments following confirm ... are of the claimed type and issues the appropriate error message and nonzero return code if they are not.

Syntax

\begin{verbatim}
confirm existence string
confirm [ new] file filename
confirm [ numeric|string|date] format string
confirm names names
confirm [ integer] number string
confirm matrix string
confirm scalar string
confirm [ new|numeric|string|str#|type] variable varlist [, exact]
\end{verbatim}

where type is \{byte|int|long|float|double|str#|strL\}

Option

exact specifies that a match be declared only if the names specified in varlist match. By default, names that are abbreviations of variables are considered to be a match.

Remarks and examples

Remarks are presented under the following headings:

\begin{verbatim}
confirm existence
confirm file
confirm format
confirm names
confirm number
confirm matrix
confirm scalar
confirm variable
\end{verbatim}

confirm is useful in \textit{do-files} and \textit{programs} when you do not want to bother issuing your own error message. confirm can also be combined with\texttt{capture} to detect and handle error conditions before they arise; also see \texttt{[P] capture}.
confirm existence

confirm existence displays the message “' ' found where something expected” and produces a return code of 6 if string does not exist.

confirm file

confirm file verifies that filename exists and is readable and issues the appropriate error message and return code if not.

confirm new file verifies that filename does not exist and that filename could be opened for writing, and issues the appropriate error message and return code if not.

The possible error messages and return codes are

<table>
<thead>
<tr>
<th>Message</th>
<th>Return code</th>
</tr>
</thead>
<tbody>
<tr>
<td>___ found where filename expected</td>
<td>7</td>
</tr>
<tr>
<td>file ___ not found</td>
<td>601</td>
</tr>
<tr>
<td>file ___ already exists</td>
<td>602</td>
</tr>
<tr>
<td>file ___ could not be opened</td>
<td>603</td>
</tr>
</tbody>
</table>

Return codes of 7 and 603 are possible for both confirm file and confirm new file. For confirm new file, a return code of 603 indicates that the filename is invalid, the specified directory does not exist, or the directory permissions do not allow you to create a new file. For instance, even if filename does not exist, confirm new file newdir\newfile will generate an error if newdir does not exist and if you do not have permissions to create a file in newdir. confirm new file filename will fail if you do not have adequate permissions to create a new file in the current working directory.

confirm format

confirm format verifies that string is a valid variable display format. It produces the message

'string' found where format expected

with a return code of 7 if the format is not valid. It produces the message

'' found where format expected

with a return code of 7 if the format is empty.

confirm numeric format specifies that the argument must be a valid numeric format. Valid numeric formats are general, fixed, and exponential. If not, it produces a return code of 7 and the message

'string' found where numeric format expected

or

'' found where numeric format expected

if string is empty.
confirm string format specifies that the argument must be a valid string format. If not, it produces a return code of 7 and the message

\[ \text{'string'} \text{ found where string format expected} \]

or

\[ \text{''} \text{ found where string format expected} \]

if string is empty.

confirm date format specifies that the argument must be a valid date format. If not, it produces a return code of 7 and the message

\[ \text{'string'} \text{ found where date format expected} \]

or

\[ \text{''} \text{ found where date format expected} \]

if string is empty.

**confirm names**

confirm names verifies that the argument or arguments are valid names according to Stata’s naming conventions. It produces the message

\[ \{\text{name} \mid \text{nothing}\} \text{ invalid name} \]

with a return code of 7 if the names are not valid.

**confirm number**

confirm number verifies that the argument can be interpreted as a number, such as 1, 5.2, −5.2, or 2.5e+10. It produces the message

\[ \{\text{string} \mid \text{nothing}\} \text{ found where number expected} \]

with a return code of 7 if not.

confirm integer number specifies that the argument must be an integer, such as 1 or 2.5e+10, but not 5.2 or −5.2. If not, it produces a return code of 7 and a slight variation on the message above:

\[ \{\text{string} \mid \text{nothing}\} \text{ found where integer expected} \]
**confirm matrix**

confirm matrix verifies that *string* is a matrix. It produces the message

```
matrix string not found
```

with a return code of 111 if *string* is not a matrix.

**confirm scalar**

confirm scalar verifies that *string* is a scalar. It produces the message

```
scalar string not found
```

with a return code of 111 if *string* is not a scalar.

**confirm variable**

confirm variable verifies that *varlist* can be interpreted as an existing varlist of any types of variables. If not, the appropriate error message and nonzero return code are returned:

<table>
<thead>
<tr>
<th>Message</th>
<th>Return code</th>
</tr>
</thead>
<tbody>
<tr>
<td>___ found where numeric variable expected</td>
<td>7</td>
</tr>
<tr>
<td>___ found where string variable expected</td>
<td>7</td>
</tr>
<tr>
<td>___ found where str# variable expected</td>
<td>7</td>
</tr>
<tr>
<td>___ found where strL variable expected</td>
<td>7</td>
</tr>
<tr>
<td>no variables defined</td>
<td>111</td>
</tr>
<tr>
<td>variable ___ not found</td>
<td>111</td>
</tr>
<tr>
<td>___ invalid name</td>
<td>198</td>
</tr>
</tbody>
</table>

confirm numeric variable specifies that all the variables are numeric. If the variable exists but is not numeric, Stata displays the message

```
'varname' found where numeric variable expected
```

or

```
'' found where numeric variable expected
```

with a return code of 7 if *varlist* is not specified.

confirm string variable specifies that all the variables are strings, meaning *str#* or *strL*. If the variable exists but is not a string variable, Stata displays the message

```
'varname' found where string variable expected
```

or

```
'' found where string variable expected
```

with a return code of 7 if *varlist* is not specified.
confirm str# variable specifies that all the variables are str#, such as str10 or str42, but are not strLs.

confirm type variable specifies that all variables are of the indicated storage type. For example, confirm int variable myvar, confirm float variable myvar thatvar, or confirm strL variable blobvar. As with confirm string variable, the appropriate message and return code of 7 are possible.

confirm new variable verifies that varlist can be interpreted as a new varlist. The possible messages and return codes are

<table>
<thead>
<tr>
<th>Message</th>
<th>Return code</th>
</tr>
</thead>
<tbody>
<tr>
<td>___ found where varname expected</td>
<td>7</td>
</tr>
<tr>
<td>___ already defined</td>
<td>110</td>
</tr>
<tr>
<td>___ invalid name</td>
<td>198</td>
</tr>
</tbody>
</table>

➢ Example 1

confirm is a cheap way to include minimal syntax checking in your programs. For instance, you have written a program that is supposed to take a one-integer argument. Although you do not have to include any syntax checking at all—the program will probably fail with some error if the argument is incorrect—it is safer to add one line at the top of the program:

```plaintext
    confirm integer number '1'
```

Now if the first argument is not an integer, you will get a reasonable error message, and the program will stop automatically.

➢ Example 2

More sophisticated programs often combine the confirm and capture commands. For instance, ttest has a complex syntax: if the user types ttest var=5, it tests that the mean of var is 5 using one set of formulas, and if the user types ttest var=var2, it tests equality of means by using another set of formulas. Whether there is a number or a variable to the right of the equal sign determines which set of formulas ttest uses. This choice was done by

```plaintext
    capture confirm number 'exp'
    if _rc==0 {  
        (code for test against a constant )
         exit
    }
    (code for test of two variables)
```

Also see

[P] capture — Capture return code
**continue — Break out of loops**

### Description

The `continue` command within a `foreach`, `forvalues`, or `while` loop breaks execution of the current loop iteration and skips the remaining commands within the loop. Execution resumes at the top of the loop unless the `break` option is specified, in which case execution resumes with the command following the looping command. See [P] foreach, [P] forvalues, and [P] while for a discussion of the looping commands.

### Syntax

```
continue [, break]
```

### Option

`break` indicates that the loop is to be exited. The default is to skip the remaining steps of the current iteration and to resume loop execution again at the top of the loop.

### Remarks and examples

We illustrate `continue` with the `forvalues` command, but it can be used in the same way with the `foreach` and `while` commands.

#### Example 1

The following `forvalues` loop lists the odd and even numbers from one to four:

```
.c forvalues x = 1(1)4 {
  2.    if mod('x',2) {
  3.        display "'x' is odd"
  4.    }
  5.    else {
  6.        display "'x' is even"
  7.    }
  8. }
1 is odd
2 is even
3 is odd
4 is even
```
It could be coded using the `continue` command instead of `else`:

```stata
. forvalues x = 1(1)4 {
2. if mod('x',2) {
3. display "'x' is odd"
4. continue
5. }
6. display "'x' is even"
7. }
```

When `continue` is executed, any remaining statements that exist in the loop are ignored. Execution continues at the top of the loop where, here, `forvalues` sets the next value of ‘x’, compares that with 4, and then perhaps begins the loop again.

**Example 2**

`continue, break` causes execution of the loop to stop; it prematurely exits the loop.

```stata
. forvalues x = 6/1000 {
2. if mod('x',2)==0 & mod('x',3)==0 & mod('x',5)==0 {
3. display "The least common multiple of 2, 3, and 5 is 'x'"
4. continue, break
5. }
6. }
```

The least common multiple of 2, 3, and 5 is 30

Although the `forvalues` loop was scheduled to go over the values 6–1,000, the `continue, break` statement forced it to stop after 30.

Title

creturn — Return c-class values

Description

Stata’s c-class, c(), contains the values of system parameters and settings, along with certain constants such as the value of pi. c() values may be referred to but may not be assigned.

Menu

Data > Other utilities > List constants and system parameters

Syntax

creturn list

Remarks and examples

The c-class values are presented under the following headings:

- System values
- Directories and paths
- System limits
- Numerical and string limits
- Current dataset
- Memory settings
- Output settings
- Interface settings
- Graphics settings
- Efficiency settings
- Network settings
- Update settings
- Trace (program debugging) settings
- Mata settings
- Unicode settings
- Other settings
- Other

There may be other c-class values that have been added since the printing of this manual. Type help creturn for up-to-date information.

System values

c(current_date) returns the current date as a string in the format "dd Mon yyyy", where dd is the day of the month (if day is less than 10, a space and one digit are used); Mon is one of Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, or Dec; and yyyy is the four-digit year.

Examples:

1 Jan 2003
26 Mar 2007
28 Jan 2013
c(current_time) returns the current time as a string in the format "hh:mm:ss", where hh is the hour 00–23, mm is the minute 00–59, and ss is the second 00–59.

Examples:
09:42:55
13:02:01
21:15:59
c(rmsg_time) returns a numeric scalar equal to the elapsed time last reported as a result of set rmsg on; see [P] rmsg.
c(stata_version) returns a numeric scalar equal to the version of Stata that you are running. In Stata 15, this number is 15; in Stata 15.1, 15.1; and in Stata 16, 16. This is the version of Stata that you are running, not the version being mimicked by the version command.
c(version) returns a numeric scalar equal to the version currently set by the version command; see [P] version.
c(userversion) returns a numeric scalar equal to the user version currently set by the version command; see [P] version.
c(dyndoc_version) returns a numeric scalar equal to the current version of dynamic documents Stata understands how to convert. Stata can convert any dynamic document with a version less than or equal to c(dyndoc_version). The dynamic document version is set by the <<dd_version>> tag within the document.
c(born_date) returns a string in the same format as c(current_date) containing the date of the Stata executable that you are running; see [R] update.
c(flavor) returns a string containing "IC", according to the version of Stata that you are running. c(flavor) == "IC" for Stata/MP and Stata/SE, as well as for Stata/IC. Think of c(flavor) == "IC" as meaning “IC or better”, so Stata/IC and all higher flavors of Stata are considered to be “IC”.
c(bit) returns a numeric scalar equal to 64 if you are using a 64-bit version of Stata and 32 if you are using a 32-bit version of Stata.
c(SE) returns a numeric scalar equal to 1 if you are running Stata/SE or Stata/MP and returns 0 otherwise. Think of c(SE) == 1 as meaning “SE or better”, so Stata/SE and Stata/MP both return 1.
c(MP) returns a numeric scalar equal to 1 if you are running Stata/MP and 0 otherwise.
c(processors) returns a numeric scalar equal to the number of processors/cores that Stata/MP is currently set to use. It returns 1 if you are not running Stata/MP.
c(processors_lic) returns a numeric scalar equal to the number of processors/cores that your Stata/MP license allows. It returns 1 if you are not running Stata/MP.
c(processors_mach) returns a numeric scalar equal to the number of processors/cores that your computer has if you are running Stata/MP. It returns missing value (.) if you are not running Stata/MP.
c(processors_max) returns a numeric scalar equal to the maximum number of processors/cores that Stata/MP could use, which is equal to the minimum of c(processors_lic) and c(processors_mach). It returns 1 if you are not running Stata/MP.
c(mode) returns a string containing "" or "batch", depending on whether Stata was invoked in interactive mode (the usual case) or batch mode (using, perhaps, the -b option of Stata for Unix).
c(console) returns a string containing "" or "console", depending on whether you are running a windowed version of Stata or Stata(console).
c(os) returns a string containing "MacOSX", "Unix", or "Windows", depending on the operating system that you are using. The list of alternatives, although complete as of the date of this writing, may not be complete.

c(osdtl) returns an additional string, depending on the operating system, providing the release number or other details about the operating system. c(osdtl) is often "".

c(hostname) returns a string containing the name of the host machine.

c(machine_type) returns a string that describes the hardware platform, such as "PC", "PC (64-bit x86-64)", or "Macintosh (Intel 64-bit)".

c(byteorder) returns a string containing "lohi" or "hilo", depending on the byte order of the hardware. Consider a two-byte integer. On some computers, the most significant byte is written first, so x'0001' (meaning the byte 00 followed by 01) would mean the number 1. Such computers are designated "hilo". Other computers write the least-significant byte first, so x'0001' would be 256, and 1 would be x'0100'. Such computers are designated "lohi".

c(username) returns the user ID (provided by the operating system) of the user currently using Stata.

Directories and paths

Note: The directory paths returned below usually end in a directory separator, so if you wish to construct the full path name of file abc.def in directory c(...), you code

...‘c(...)’abc.def...

and not

...‘c(...)’/abc.def...

If c(...) returns a directory name that does not end in a directory separator, a special note of the fact is made.

c(sysdir_stata) returns a string containing the name of the directory in which Stata is installed. More technically, c(sysdir_stata) returns the STATA directory as defined by sysdir; see [P] sysdir.

Example: C:\Program Files\Stata15/

The above example contains no typographical errors. Under Windows, the directory name will end in forward slash. That is so you can code things such as ‘c(sysdir_stata)’‘filename’.

If c(sysdir_stata) ended in backslash, Stata's macro expander would interpret the backslash as an escape character and so not expand ‘filename’.

c(sysdir_base) returns a string containing the name of the directory in which the original official ado-files that were shipped with Stata were installed.

Example: C:\Program Files\Stata15\ado\base/

c(sysdir_site) returns a string containing the name of the directory in which user-written additions may be installed for sitewide use. More technically, c(sysdir_site) returns the SITE directory as defined by sysdir; see [P] sysdir.

Example: C:\Program Files\Stata15\ado\site/

c(sysdir_plus) returns a string containing the name of the directory in which additions written by others may be installed for personal use. More technically, c(sysdir_plus) returns the PLUS directory, as defined by sysdir; see [P] sysdir.

Example: C:\ado\plus/
c(sysdir_personal) returns a string containing the name of the directory in which additions written by you may be installed. More technically, c(sysdir_personal) returns the PERSONAL directory, as defined by sysdir; see [P] sysdir.

Example: C:\ado\personal/

c(sysdir_oldplace) identifies another directory in which user-written ado-files might be installed. c(sysdir_oldplace) maintains compatibility with very ancient versions of Stata.

c(tmpdir) returns a string containing the name of the directory used by Stata for temporary files.

Example: /tmp

c(adopath) returns a string containing the directories that are to be searched when Stata is attempting to locate an ado-file. The path elements are separated by a semicolon (;), and the elements themselves may be directory names, "." to indicate the current directory, or sysdir references.

Example: BASE;SITE;;PERSONAL;PLUS;OLDPLACE

c(pwd) returns a string containing the current (working) directory.

Example: C:\data

Notice that c(pwd) does not end in a directory separator, so in a program, to save the name of the file abc.def prefixed by the current directory (for example, because you were about to change directories and still wanted to refer to the file), you would code

```
local file "'c(pwd)'/abc.def"
```

or

```
local file "'c(pwd)''c(dirsep)'abc.def"
```

The second form is preferred if you want to construct “pretty” filenames, but the first form is acceptable because Stata understands a forward slash (/) as a directory separator.

c(dirsep) returns a string containing "/".

Example: /

For Windows operating systems, a forward slash (/) is returned rather than a backslash (\). Stata for Windows understands both, but in programs, use of the forward slash is recommended because the backslash can interfere with Stata’s interpretation of macro expansion characters. Do not be concerned if the result of your code is a mix of backslash and forward slash characters, such as \a\b\myfile.dta; Stata will understand it just as it would understand /a/b/myfile.dta or \a\b\myfile.dta.

System limits

c(max_N_theory) returns a numeric scalar reporting the maximum number of observations allowed.

```
c(max_N_theory) reports the maximum number of observations that Stata can process if it has enough memory. This is usually 2,147,483,647 for Stata/SE and Stata/IC and is 1,099,511,627,775 for Stata/MP.
```

c(max_k_theory) returns a numeric scalar reporting the maximum number of variables allowed. If you have Stata/MP or Stata/SE, you can change this number with set maxvar; see [D] memory.

c(max_width_theory) returns the theoretical maximum width allowed. The width of a dataset is defined as the sum of the byte lengths of its individual variables. If you had a dataset with two int variables, three floats, one double, and a str20 variable, the width of the dataset would be $2 \times 2 + 3 \times 4 + 8 + 20 = 44$ bytes.
c(max_matsize) and c(min_matsize) each return a numeric scalar reporting the maximum and minimum values to which matsize may be set. If the version of Stata you are running does not allow the setting of matsize, the two values will be equal. c(matsize), documented under Memory settings below, returns the current value of matsize.

c(max_macrolen) and c(macrolen) each return a numeric scalar reporting the maximum length of macros. c(max_macrolen) and c(macrolen) may not be equal under Stata/MP or Stata/SE and will be equal otherwise. For Stata/MP or Stata/SE, macrolen is set according to maxvar: the length is long enough to hold a macro referring to every variable in the dataset.

c(charlen) returns a numeric scalar reporting the maximum length of a characteristic.

c(max_cmdlen) and c(cmdlen) each return a numeric scalar reporting the maximum length of a Stata command. c(max_cmdlen) and c(cmdlen) may not be equal under Stata/MP or Stata/SE and will be equal otherwise. For Stata/MP or Stata/SE, cmdlen is set according to maxvar: the length is long enough to hold a command referring to every variable in the dataset.

c(name_lenbyte) returns a numeric scalar equal to 128, which is the current maximum length in bytes of names in Stata.

c(name_lenchar) returns a numeric scalar equal to 32, which is the current maximum length in Unicode characters of names in Stata.

c(eqlen) returns the maximum length that Stata allows for equation names.

Numerical and string limits

c(mindouble), c(maxdouble), and c(epsdouble) each return a numeric scalar. c(mindouble) is the largest negative number that can be stored in the 8-byte double storage type. c(maxdouble) is the largest positive number that can be stored in a double. c(epsdouble) is the smallest nonzero, positive number (epsilon) that, when added to 1 and stored as a double, does not equal 1.

c(smallestdouble) returns a numeric scalar containing the smallest full-precision double that is bigger than zero. There are smaller positive values that can be stored; these are denormalized numbers. Denormalized numbers do not have full precision.

c(minfloat), c(maxfloat), and c(epsfloat) each return a numeric scalar that reports for the 4-byte float storage type what c(mindouble), c(maxdouble), and c(epsdouble) report for double.

c(minlong) and c(maxlong) return scalars reporting the largest negative number and the largest positive number that can be stored in the 4-byte, integer long storage type. There is no c(epslong), but if there were, it would return 1.

c(minint) and c(maxint) return scalars reporting the largest negative number and the largest positive number that can be stored in the 2-byte, integer int storage type.

c(minbyte) and c(maxbyte) return scalars reporting the largest negative number and the largest positive number that can be stored in the 1-byte, integer byte storage type.

(c(maxstrvarlen) returns the longest str# string storage type allowed, which is 2045. Do not confuse c(maxstrvarlen) with c(macrolen). c(maxstrvarlen) corresponds to string variables stored in the data.

c(maxstrlvarlen) returns the length of the longest string that can be stored in a strL, which is 2,000,000,000.

c(maxvlabellen) returns the maximum length for one value label string, which is 32,000.
Current dataset

c(N) returns a numeric scalar equal to \_N, the number of observations in the dataset in memory. In an expression, it makes no difference whether you refer to \_N or c(N). However, when used in expressions with the by prefix, c(N) does not change with the by-group like \_N.

The advantage of c(N) is in nonexpression contexts. Say that you are calling a subroutine, mysub, which takes as an argument the number of observations in the dataset. Then you could code

```
local nobs = \_N
mysub 'nobs'
```

or

```
mysub 'c(N)'
```

The second requires less typing.

c(k) returns a numeric scalar equal to the number of variables in the dataset in memory. c(k) is equal to r(k), which is returned by describe.

c(width) returns a numeric scalar equal to the width, in bytes, of the dataset in memory. If you had a dataset with two int variables, three floats, one double, and a str20 variable, the width of the dataset would be $2 \times 2 + 3 \times 4 + 8 + 20 = 44$ bytes. c(width) is equal to r(width), which is returned by describe.

c(changed) returns a numeric scalar equal to 0 if the dataset in memory has not changed since it was last saved and 1 otherwise. c(changed) is equal to r(changed), which is returned by describe.

c(filename) returns a string containing the filename last specified with a use or save, such as "C:\Data\auto.dta". c(filename) is equal to $S\_FN$.

c(filedate) returns a string containing the date and time the file in c(filename) was last saved, such as "7 Jul 2016 13:51". c(filedate) is equal to $S\_FNDATE$.

Memory settings

c(memory) returns a numeric scalar reporting the amount of memory, in bytes, currently allocated by Stata.

c(maxvar) returns a numeric scalar reporting the maximum number of variables currently allowed in a dataset, as set by set maxvar if you are running Stata/MP or Stata/SE. Otherwise, c(maxvar) is a constant.

c(matsize) returns a numeric scalar reporting the current value of matsize, as set by set matsize.

c(niceness) returns a numeric scalar recording how soon Stata gives back unused segments to the operating system.

c(min_memory) returns a numeric scalar recording the minimum value to which memory can be reduced when its memory is unused.

c(max_memory) returns a numeric scalar recording the maximum amount of memory that Stata may allocate.

c(segmentsize) returns a numeric scalar recording the size of the segments in which memory is allocated.
Output settings

c(more) returns a string containing "on" or "off", according to the current set more setting.
c(rmsg) returns a string containing "on" or "off", according to the current set rmsg setting.
c(dp) returns a string containing "period" or "comma", according to the current set dp setting.
c(linesize) returns a numeric scalar equal to the current set linesize setting.
c(pagesize) returns a numeric scalar equal to the current set pagesize setting.
c(logtype) returns a string containing "smcl" or "text", according to the current set logtype setting.
c(noisily) returns a numeric scalar equal to 0 if output is being suppressed and 1 if output is being displayed; see [P] quietly.
c(notifyuser) (Mac only) returns a string containing "on" or "off", according to the current set notifyuser setting.
c(playsnd) (Mac only) returns a string containing "on" or "off", according to the current set playsnd setting.
c(include_bitmap) (Mac only) returns a string containing "on" or "off", according to the current set include_bitmap setting.
c(level) returns a numeric scalar equal to the current set level setting.
c(clevel) returns a numeric scalar equal to the current set clevel setting.
c(showbaselevels) returns a string containing "", "on", "off", or "all", according to the current set showbaselevels setting. See [R] set showbaselevels.
c(showemptycells) returns a string containing "", "on", or "off", according to the current set showemptycells setting. See [R] set showbaselevels.
c(showomitted) returns a string containing "", "on", or "off", according to the current set showomitted setting. See [R] set showbaselevels.
c(fvlabel) returns a string containing "on" or "off", according to the current set fvlabel setting. See [R] set showbaselevels.
c(fvwrap) returns a numeric scalar equal to the current set fvwrap setting. See [R] set showbaselevels.
c(fvwrapon) returns a string containing "word" or "width", according to the current set fvwrapon setting. See [R] set showbaselevels.
c(fvtrack) returns a string containing "term" or "factor", according to the current set fvtrack setting.
c(lstretch) returns a string containing "", "on", or "off", according to the current set lstretch setting.
c(cformat) returns a string containing the current set cformat setting. See [R] set cformat.
c(sformat) returns a string containing the current set sformat setting. See [R] set cformat.
c(pformat) returns a string containing the current set pformat setting. See [R] set cformat.
c(coeftabresults) returns a string containing "on" or "off", according to the current set coeftabresults setting.
Interface settings

c(dockable) (Windows only) returns a string containing "on" or "off", according to the current `set dockable` setting.

c(dockingguides) (Windows only) returns a string containing "on" or "off", according to the current `set dockingguides` setting.

c(locksplitters) (Windows only) returns a string containing "on" or "off", according to the current `set locksplitters` setting.

c(pinnable) (Windows only) returns a string containing "on" or "off", according to the current `set pinnable` setting.

c(doublebuffer) (Windows only) returns a string containing "on" or "off", according to the current `set doublebuffer` setting.

c(reventries) returns a numeric scalar containing the maximum number of commands stored by the Review window.

c(fastscroll) (Unix and Windows only) returns a string containing "on" or "off", according to the current `set fastscroll` setting.

c(revkeyboard) (Mac only) returns a string containing "on" or "off", according to the current `set revkeyboard` setting.

c(varkeyboard) (Mac only) returns a string containing "on" or "off", according to the current `set varkeyboard` setting.

c(smoothfonts) (Mac only) returns a string containing "on" or "off", according to the current `set smoothfonts` setting.

c(linegap) returns a numeric scalar equal to the current `set linegap` setting. If `set linegap` is irrelevant under the version of Stata that you are running, `c(linegap)` returns a system missing value.

c(scrollbufsize) returns a numeric scalar equal to the current `set scrollbufsize` setting. If `set scrollbufsize` is irrelevant under the version of Stata that you are running, `c(scrollbufsize)` returns a system missing value.

c(maxdb) returns a numeric scalar containing the maximum number of dialog boxes whose contents are remembered from one invocation to the next during a session; see [R] db.

Graphics settings

c(graphics) returns a string containing "on" or "off", according to the current `set graphics` setting.

c(autotabgraphs) (Windows only) returns a string containing "on" or "off", according to the current `set autotabgraphs` setting.

c(scheme) returns the name of the current `set scheme` setting.

c(printcolor) returns "automatic", "asis", "gs1", "gs2", or "gs3", according to the current `set printcolor` setting.

c(copycolor) (Mac and Windows only) returns "automatic", "asis", "gs1", "gs2", or "gs3", according to the current `set copycolor` setting.
Efficiency settings

\( c(\text{adosize}) \) returns a numeric scalar equal to the current \texttt{set adosize} setting.

Network settings

\( c(\text{checksum}) \) returns a string containing "on" or "off", according to the current \texttt{set checksum} setting.
\( c(\text{timeout1}) \) returns a numeric scalar equal to the current \texttt{set timeout1} setting.
\( c(\text{timeout2}) \) returns a numeric scalar equal to the current \texttt{set timeout2} setting.
\( c(\text{httpproxy}) \) returns a string containing "on" or "off", according to the current \texttt{set httpproxy} setting.
\( c(\text{httpproxyhost}) \) returns a string containing the name of the proxy host or "" if no proxy host is set. \( c(\text{httpproxyhost}) \) is relevant only if \( c(\text{httpproxy}) = "on"\).
\( c(\text{httpproxyport}) \) returns a numeric scalar equal to the proxy port number. \( c(\text{httpproxyport}) \) is relevant only if \( c(\text{httpproxy}) = "on"\).
\( c(\text{httpproxyauth}) \) returns a string containing "on" or "off", according to the current \texttt{set httpproxyauth} setting. \( c(\text{httpproxyauth}) \) is relevant only if \( c(\text{httpproxy}) = "on"\).
\( c(\text{httpproxyuser}) \) returns a string containing the name of the proxy user, if one is set, or "" otherwise. \( c(\text{httpproxyuser}) \) is relevant only if \( c(\text{httpproxy}) = "on" \) and \( c(\text{httpproxyauth}) = "on"\).
\( c(\text{httpproxypw}) \) returns a string containing "*" if a password is set or "" otherwise. \( c(\text{httpproxypw}) \) is relevant only if \( c(\text{httpproxy}) = "on" \) and \( c(\text{httpproxyauth}) = "on"\).

Update settings

\( c(\text{update_query}) \) (Mac and Windows only) returns a string containing "on" or "off", according to the current \texttt{set update_query} setting.
\( c(\text{update_interval}) \) (Mac and Windows only) returns a numeric scalar containing the current \texttt{set update_interval} setting.
\( c(\text{update_prompt}) \) (Mac and Windows only) returns a string containing "on" or "off", according to the current \texttt{set update_prompt} setting.

Trace (program debugging) settings

\( c(\text{trace}) \) returns a string containing "on" or "off", according to the current \texttt{set trace} setting.
\( c(\text{tracedepth}) \) returns a numeric scalar reporting the current \texttt{set tracedepth} setting.
\( c(\text{tracesep}) \) returns a string containing "on" or "off", according to the current \texttt{set tracesep} setting.
\( c(\text{traceindent}) \) returns a string containing "on" or "off", according to the current \texttt{set traceindent} setting.
\( c(\text{traceexpand}) \) returns a string containing "on" or "off", according to the current \texttt{set traceexpand} setting.
c(tracenumber) returns a string containing "on" or "off", according to the current set tracenumber setting.

c(tracehilite) returns a string containing "pattern", according to the current set tracehilite setting.

**Mata settings**

c(matastrict) returns a string containing "on" or "off", according to the current set matastrict setting.

c(matalnum) returns a string containing "on" or "off", according to the current set matalnum setting.

c(mataoptimize) returns a string containing "on" or "off", according to the current set mataoptimize setting.

c(matafavor) returns a string containing "space" or "speed", according to the current set matafavor setting.

c(matacache) returns a numeric scalar containing the maximum amount of memory, in kilobytes, that may be consumed before Mata starts looking to drop autoloaded functions that are not currently being used.

c(matalibs) returns a string containing the names in order of the .mlib libraries to be searched; see [M-1] how.

c(matamofirst) returns a string containing "on" or "off", according to the current set matamofirst setting.

**Unicode settings**

c(locale_ui) returns a string containing the locale that specifies the localization package for the user interface. See [P] set locale_ui.

c(locale_functions) returns a string containing the default locale for string functions. See [P] set locale_functions.

c(locale_icudflt) returns a string containing the default ICU locale. See [U] 12.4.2.4 Locales in Unicode.

**Other settings**

c(type) returns a string containing "float" or "double", according to the current set type setting.

c(maxiter) returns a numeric scalar equal to the current set maxiter setting.

c(searchdefault) returns a string containing "local", "net", or "all", according to the current search default setting.

c(rng) returns a string containing the current set rng setting. This controls which random-number generator Stata will use. Possible values are "mt64", which specifies to always use the 64-bit Mersenne Twister random-number generator; "mt64s", which specifies to always use the 64-bit Mersenne Twister stream random-number generator; "kiss32", which specifies to always use the 32-bit KISS (keep it simple stupid) random-number generator; or "default", which specifies to
let Stata choose between these random-number generators based on version control. Stata’s default random-number generator in the absence of version control and with `set rng default` is the 64-bit Mersenne Twister. See `[R] set rng`.

c(rng_current) returns a string containing the random-number generator currently in effect, that is, "mt64", "mt64s", or "kiss32", depending on the current `set rng` setting. If `set rng` is currently set to "default", then `c(rng_current)` depends on the current user version. See `[P] version`.

c(rngstate) returns a string containing the current state of the `runiform()` random-number generator. You can initialize the state of the random-number generator with `set seed`, and you can restore the state of the random-number generator to a saved state with `set rngstate`. See `[R] set seed`.

c(rngseed_mt64s) returns the seed last set for the stream random-number generator (mt64s). See `[R] set rngstream`.

c(rngstream) returns the current stream of the stream random-number generator (mt64s). See `[R] set rngstream`.

c(varabbrev) returns a string containing "on" or "off", according to the current `set varabbrev` setting.

c(emptycells) returns a string containing "keep" or "drop", according to the current `set emptycells` setting.

c(haverdir) (Windows only) returns a string containing the name of the directory that you specified to contain the Haver databases; see `set haverdir` in `[D] import haver`.

c(odbcmgr) (Mac and Unix only) returns a string containing "iodbc" or "unixodbc", according to the current `set odbcmgr` setting.

c(odbcdriver) returns a string containing "unicode" or "ansi", according to the current `set odbcdriver` setting.

c(fredkey) returns the current API key, according to the current `set fredkey` setting.

Other

`c(pi)` returns a numerical scalar equal to _pi_, the value of the ratio of the circumference to the diameter of a circle. In an expression context, it makes no difference whether you use `c(pi)` or `_pi_. `c(pi)`, however, may be used (enclosed in single quotes) in other contexts.

c(alpha) returns a string containing "a b c d e f g h i..".

c(ALPHA) returns a string containing "A B C D E F G H I..".

c(Mons) returns a string containing "Jan Feb Mar Apr M..".

c(Months) returns a string containing "January February ..".

c(Wdays) returns a string containing "Sun Mon Tue Wed T..".

c(Weekdays) returns a string containing "Sunday Monday Tue..".

c(rc) returns a numerical scalar equal to _rc_, the value set by the `capture` command. In an expression context, it makes no difference whether you use `c(rc)` or `_rc_. `c(rc)`, however, may be used (enclosed in single quotes) in other contexts. This is less important than it sounds because you could just as easily type `='-_rc'`.

[P] return — Return stored results

[R] query — Display system parameters

[R] set — Overview of system parameters
_datasignature — Determine whether data have changed

Description

_datasignature calculates, displays, and stores in \texttt{r(datasignature)} checksums of the data, forming a signature. A signature might be

\begin{verbatim}
162:11(12321):2725060400:4007406597
\end{verbatim}

The signature can be stored and later used to determine whether the data have changed.

Syntax

\begin{verbatim}
_datasignature [varlist] [if] [in] [, options]
\end{verbatim}

options Description
\begin{itemize}
\item \texttt{fast} perform calculation in machine-dependent way
\item \texttt{esample} restrict to estimation sample
\item \texttt{nonames} do not include checksum for variable names
\item \texttt{nодеfault} treat empty \texttt{varlist} as null
\end{itemize}

Options

\texttt{fast} specifies that the checksum calculation be made in a faster, less computationally intensive, and machine-dependent way. With this option, \_datasignature runs faster on all computers and can run in less than one-third of the time on some computers. The result can be compared with other \texttt{fast} computations made on the same computer, and computers of the same make, but not across computers of different makes. See \textit{Remarks and examples} below.

\texttt{esample} specifies that the checksum be calculated on the data for which \texttt{e(sample)} = 1. Coding

\begin{verbatim}
_datasignature 'varlist', esample
\end{verbatim}

or

\begin{verbatim}
_datasignature 'varlist' if e(sample)
\end{verbatim}

produces the same result. The former is a little quicker. If the \texttt{esample} option is specified, if \texttt{exp} may not be specified.

\texttt{nonames} specifies that the variable-names checksum in the signature be omitted. Rather than the signature being 74:12(71728):2814604011:3381794779, it would be 74:12:2814604011:3381794779. This option is useful when you do not care about the names or you know that the names have changed, such as when using temporary variables.
nodefault specifies that when `varlist` is not specified, it be taken to mean no variables rather than all variables in the dataset. Thus you may code

    _datasignature `modelvars', nodefault

and obtain desired results even if `modelvars` expands to nothing.

Remarks and examples

For an introduction to data signatures, see [D] datasignature. To briefly summarize:

- A signature is a short string that is calculated from a dataset, such as 74:12(71728):3831085005:1395876116. If a dataset has the same signature at two different times, then it is highly likely that the data have not changed. If a dataset has a different signature, then it is certain that the data have changed.

- An example data signature is 74:12(71728):3831085005:1395876116. The components are
  a. 74, the number of observations;
  b. 12, the number of variables;
  c. 71728, a checksum function of the variable names and the order in which they occur; and
  d. 3831085005 and 1395876116, checksum functions of the values of the variables, calculated two different ways.

- Signatures are functions of
  a. the number of observations and number of variables in the data;
  b. the values of the variables;
  c. the names of the variables;
  d. the order in which the variables occur in the dataset if `varlist` is not specified, or in `varlist` if it is; and
  e. the storage types of the variables.

If any of these change, the signature changes. The signature is not a function of the sort order of the data. The signature is not a function of variable labels, value labels, contents of characteristics, and the like.

Programs sometimes need to verify that they are running on the same data at two different times. This verification is especially common with estimation commands, where the estimation is performed by one command and postestimation analyses by another. To ensure that the data have not changed, one obtains the signature at the time of estimation and then compares that with the signature obtained when the postestimation command is run. See [P] signestimationsample for an example.

If you are producing signatures for use within a Stata session—signatures that will not be written to disk and thus cannot possibly be transferred to different computers—specify _datasignature's `fast` option. On some computers, _datasignature can run in less than one-third of the time if this option is specified.

    _datasignature, fast

is faster for two reasons: (1) the option uses a less computationally intensive algorithm and (2) the computation is made in a machine-dependent way. The first affects the quality of the signature, and the second does not.
Remember that signatures have two checksums for the data. When _fast_ is specified, a different, inferior algorithm is substituted for the second checksum. In the _fast_ case, the second signature is not conditionally independent of the first and thus does not provide 48 bits of additional information; it probably provides around 24 bits. The default second checksum calculation was selected to catch problems that the first calculation does not catch. In the _fast_ case, the second checksum does not have that property. These details make the _fast_ signature sound markedly inferior. Nevertheless, the first checksum calculation, which is used both in the default and the _fast_ cases, is good, and when _datasignature_ was written, we considered using only the first calculation in both cases. We believe that, for within-session testing, where one does not have to guard against changes produced by an intelligent enemy who may be trying to fool you, the first checksum alone is adequate. The inferior second checksum we include in the _fast_ case provides more protection than we think necessary.

The second difference has nothing to do with quality. Modern computers come in two types: those that record least-significant bytes (LSBs) first and those that record most-significant bytes (MSBs) first. Intel-based computers, for instance, are usually LSB, whereas Sun computers are MSB.

By default, _datasignature_ makes the checksum calculation in an LSB way, even on MSB computers. MSB computers must therefore go to extra work to emulate the LSB calculation, and so _datasignature_ runs slower on them.

When you specify _fast_, _datasignature_ calculates the checksum the native way. The checksum is every bit as good, but the checksum produced will be different on MSB computers. If you merely store the signature in memory for use later in the session, however, that does not matter.

**Stored results**

.datasignature stores the following in r():

Macros

r(datasignature) the signature

[D] datasignature — Determine whether data have changed

[P] signestimationsample — Determine whether the estimation sample has changed

[D] compare — Compare two variables

[D] cf — Compare two datasets
#delimit — Change delimiter

Description

The #delimit command resets the character that marks the end of a command. It can be used only in do-files or ado-files.

Syntax

```
#delimit { cr | ; }
```

Remarks and examples

#delimit (pronounced pound-delimit) is a Stata preprocessor command. #commands do not generate a return code, nor do they generate ordinary Stata errors. The only error message associated with #commands is “unrecognized #command”.

Commands given from the console are always executed when you press the Enter, or Return, key. #delimit cannot be used interactively, so you cannot change Stata’s interactive behavior.

Commands in a do-file, however, may be delimited with a carriage return or a semicolon. When a do-file begins, the delimiter is a carriage return. The command ‘#delimit ;’ changes the delimiter to a semicolon. To restore the carriage return delimiter inside a file, use #delimit cr.

When a do-file begins execution, the delimiter is automatically set to carriage return, even if it was called from another do-file that set the delimiter to semicolon. Also, the current do-file need not worry about restoring the delimiter to what it was because Stata will do that automatically.

Example 1

```
/*
   When the do-file begins, the delimiter is carriage return:
*/
use basedata, clear
/*
   The last command loaded our data.
   Let’s now change the delimiter:
*/
#delimit ;
summarize sex
   salary ;
/*
   Because the delimiter is semicolon, it does not matter that our
   command took two lines.
   We can change the delimiter back:
*/
```
#delimit cr
summarize sex salary
/*
   Now our lines once again end on return. The semicolon delimiter
   is often used when loading programs:
*/
capture program drop fix
program fix
   confirm var '1'
   #delimit ;
   replace '1' = . if salary>=. | salary==0 | hours>=. | hours==0 ;
   #delimit cr
end
fix var1
fix var2

Technical note

Just because you have long lines does not mean that you must change the delimiter to semicolon. Stata does not care that the line is long. There are also other ways to indicate that more than one physical line is one logical line. One popular choice is ///:

   replace '1' = . if salary>=. | salary==0 | ///
       hours>=. | hours==0

4. SCRIPT
5. PROGRAM
   5.1 Concepts
      5.1.1 Vnames
1. Introduction

At a programming level, the purpose of a dialog box is to produce a Stata command to be executed. Along the way, it hopefully provides the user with an intuitive and consistent experience—that is your job as a dialog-box programmer—but the ultimate output will be

```
list mpg weight or
regress mpg weight if foreign or
append using myfile
```
or whatever other Stata command is appropriate. Dialog boxes are limited to executing one Stata command, but that does not limit what you can do with them because that Stata command can be an ado-file. (Actually, there is another way around the one-command limit, which we will discuss in 5.1.3 rstrings: cmdstring and optstring.)

This ultimate result is called the dialog box’s u-action.

The u-action of the dialog box is determined by the code you write, called dialog code, which you store in a .dlg file. The name of the .dlg file is important because it determines the name of the dialog box. When a user types

```
.db regress
```
regress.dlg is executed. Stata finds the file the same way it finds ado-files—by looking along
the ado-path; see [P] sysdir. regress.dlg runs regress commands because of the dialog code that
appears inside the regress.dlg file. regress.dlg could just as well execute probit commands
or even merge commands if the code were written differently.

.dlg files describe
1. how the dialogs look;
2. how the input controls of the dialogs interact with each other; and
3. how the u-action is constructed from the user’s input.

Items 1 and 2 determine how intuitive and consistent the user finds the dialog. Item 3 determines
what the dialog box does. Item 2 determines whether some fields are disabled or hidden so that they
cannot be mistakenly filled in until the user clicks on something, checks something, or fills in a
certain result.

2. Concepts

A dialog box is composed of many elements called controls, including static text, edit fields, and
checkboxes. Input controls are those that the user fills in, such as checkboxes and text-entry fields.
Static controls are fixed text and lines that appear on the dialog box but that the user cannot change.
See Appendix A below for definitions of the various types of controls as well as other related jargon.

In the jargon we use, a dialog box is composed of dialogs, and dialogs are composed of controls.
When a dialog box contains multiple dialogs, only one dialog is shown at a time. Here access to the
dialogs is made possible through small tabs. Clicking on the tab associated with a dialog makes that
dialog active.

The dialog box may contain the helper buttons Help (shown as a small button with a question
mark on it) and Reset (shown as a small button with an R on it). These buttons appear in the dialog
box—not the individual dialogs—so in a multiple-dialog dialog box, they appear regardless of the
dialog (tab) selected.

The Help helper button displays a help file associated with the dialog box.

The Reset helper button resets the dialog box to its initial state. Each time a user invokes a
particular dialog box, it will remember the values last set for its controls. The reset button allows the
user to restore the default values for all controls in the dialog box.

The dialog box may also include the u-action buttons OK, Submit, Copy, and Cancel. Like
the helper buttons, u-action buttons appear in the dialog box—not the individual dialogs—so in a
multiple-dialog dialog box, they appear regardless of the dialog (tab) selected.

The OK u-action button constructs the u-action, sends it to Stata for execution, and closes the
dialog box.

The Submit u-action button constructs the u-action, sends it to Stata for execution, and leaves the
dialog box open.

The Copy u-action button constructs the u-action, sends it to the clipboard, and leaves the dialog
box open.

The Cancel u-action button closes the dialog box without constructing the u-action.

A dialog box does not have to include all of these u-action buttons, but it needs at least one.
Thus the nesting is

Dialog box, which contains
   Dialog 1, which contains
      input controls and static controls
   Dialog 2, which is optional and which, if defined, contains
      input controls and static controls

[...]

Helper buttons, which are optional and which, if defined, contain
   [Help button]
   [Reset button]

U-action buttons, which contain
   [OK button]
   [Submit button]
   [Copy button]
   [Cancel button]

Said differently,

1. a dialog box must have at least one dialog, must have one set of u-action buttons, and may have helper buttons;
2. a dialog must have at least one control and may have many controls; and
3. the u-action buttons may include any of OK, Submit, Copy, and Cancel and must include at least one of them.

Here is a simple .dlg file that will execute the kappa command, although it does not allow if exp and in range:

```plaintext
BEGIN mykappa.dlg

// ----------------- set version number and define size of box ---------
VERSION 15.0
POSITION . . 290 200

// ------------------------------------------- define a dialog ---------
DIALOG main, label("kappa - Interrater agreement")
BEGIN
   TEXT tx_var 10 10 270 ., label("frequency variables:")
   VARLIST vl_var @ +20 @ ., label("frequencies")
END

// -------------------- define the u-action and helper buttons ---------
OK ok1, label("OK")
CANCEL can1, label("Cancel")
SUBMIT sub1, label("Submit")
COPY copy1,
HELP hlp1, view("help kappa")
RESET res1

// --------------------------- define how to assemble u-action ---------
PROGRAM command
BEGIN
   put "kappa 
      varlist main.vl_var
END
```

END mykappa.dlg
2.1 Organization of the .dlg file

A .dlg file consists of seven parts, some of which are optional:

```
<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>version number</td>
</tr>
<tr>
<td>2</td>
<td>set size of dialog box</td>
</tr>
<tr>
<td>3</td>
<td>common definitions</td>
</tr>
<tr>
<td>4</td>
<td>dialog definitions</td>
</tr>
<tr>
<td>5</td>
<td>i-action definitions</td>
</tr>
<tr>
<td>6</td>
<td>u-action and helper button definitions</td>
</tr>
<tr>
<td>7</td>
<td>u-action definition</td>
</tr>
</tbody>
</table>
```

The VERSION statement must appear at the top; the other parts may appear in any order.

I-actions, mentioned in Part 5, are intermediate actions, such as hiding or showing, disabling or enabling a control, or opening the Viewer to display something, etc., while leaving the dialog up and waiting for the user to fill in more or press a u-action button.

2.2 Positions, sizes, and the DEFINE command

Part of specifying how a dialog appears is defining where things go and how big they are.

Positions are indicated by a pair of numbers, \( x \) and \( y \). They are measured in pixels and are interpreted as being measured from the top-left corner: \( x \) is how far to the right, and \( y \) is how far down.
Sizes are similarly indicated by a pair of numbers, \( x_{\text{size}} \) and \( y_{\text{size}} \). They, too, are measured in pixels and indicate the size starting at the top-left corner of the object.

Any command that needs a position or a size always takes all four numbers—position and size—and you must specify all four. In addition to each element being allowed to be a number, some extra codes are allowed. A position or size element is defined as

\[
# \quad \text{any unsigned integer number, such as 0, 1, 10, 200, \ldots}
\]

. (period) meaning the context-specific default value for this position or size element. . is allowed only with heights of controls (heights are measured from the top down) and for the initial position of a dialog box.

\[@\quad \text{means the previous value for this position or size element. If @}\text{ is used for an } x \text{ or a } y, \text{ then the } x \text{ or } y \text{ from the preceding command will be used. If @}\text{ is used for an } x_{\text{size}} \text{ or a } y_{\text{size}} \text{, then the previous } x_{\text{size}} \text{ or } y_{\text{size}} \text{ will be used.}
\]

\[+\#\quad \text{means a positive offset from the last value (meaning to the right or down or bigger). If } +10 \text{ is used for } x, \text{ the result will be 10 pixels to the right of the previous position. If } +10 \text{ is used for a } y_{\text{size}}, \text{ it means 10 pixels taller.}
\]

\[-\#\quad \text{means a negative offset from the last value (meaning to the left or up or smaller). If } -10 \text{ is used for } y, \text{ the result will be 10 pixels above the previous position. If } -10 \text{ is used for a } x_{\text{size}}, \text{ it means 10 pixels narrower.}
\]

\[\text{name} \quad \text{means the value last recorded for } name \text{ by the DEFINE command.}
\]

The DEFINE command has the syntax

\[
\text{DEFINE } name \{ . | # | +# | -# | @x | @y | @x_{\text{size}} | @y_{\text{size}} \}
\]

and may appear anywhere in your dialog code, even inside the BEGIN/END of DIALOG. Anywhere you need to specify a position or size element, you can use a \text{name} defined by DEFINE.

The first four possibilities for defining \text{name} have the obvious meaning: . means the default, \# means the number specified, +\# means a positive offset, and -\# means a negative offset. The other four possibilities—@\text{x}, @y, @x_{\text{size}}, and @y_{\text{size}}—refer to the previous \( x, y, x_{\text{size}}, \) and \( y_{\text{size}} \) values, with “previous” meaning previous to the time the DEFINE command was issued.

### 2.3 Default values

You can also load input controls with initial, or default, values. For instance, perhaps, as a default, you want one checkbox checked and another unchecked, and you want an edit field filled in with “Default title”.

The syntax of the CHECKBOX command, which creates checkboxes, is

\[
\text{CHECKBOX \ldots } [ , \ldots \text{ default(defnumval)} \ldots ]
\]

In checkboxes, the default() option specifies how the box is to be filled in initially, and 1 corresponds to checked and 0 to unchecked.

The syntax of EDIT, which creates edit fields, is

\[
\text{EDIT \ldots } [ , \ldots \text{ default(defstrval)} \ldots ]
\]

In edit fields, default() specifies what the box will contain initially.
Wherever `defnumval` appears in a syntax diagram, you may type

<table>
<thead>
<tr>
<th>defnumval</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#</code></td>
<td>meaning the number specified</td>
</tr>
<tr>
<td><code>literal #</code></td>
<td>same as <code>#</code></td>
</tr>
<tr>
<td><code>c(name)</code></td>
<td>value of <code>c(name)</code>; see [P] return</td>
</tr>
<tr>
<td><code>r(name)</code></td>
<td>value of <code>r(name)</code>; see [P] return</td>
</tr>
<tr>
<td><code>e(name)</code></td>
<td>value of <code>e(name)</code>; see [P] return</td>
</tr>
<tr>
<td><code>s(name)</code></td>
<td>value of <code>s(name)</code>; see [P] return</td>
</tr>
<tr>
<td><code>global name</code></td>
<td>value of global macro <code>$name</code></td>
</tr>
</tbody>
</table>

Wherever `defstrval` appears in a syntax diagram, you may type

<table>
<thead>
<tr>
<th>defstrval</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>string</code></td>
<td>meaning the string specified</td>
</tr>
<tr>
<td><code>literal string</code></td>
<td>same as <code>string</code></td>
</tr>
<tr>
<td><code>c(name)</code></td>

<tr>
<td><code>char varname[charname]</code></td>
<td>contents of characteristic; see [P] char</td>
</tr>
<tr>
<td><code>global name</code></td>
<td>contents of global macro <code>$name</code></td>
</tr>
</tbody>
</table>

Note: If `string` is enclosed in double quotes (simple or compound), the first set of quotes is stripped.

List and combo boxes present the user with a list of items from which to choose. In dialog-box jargon, rather than having initial or default values, the boxes are said to be populated. The syntax for creating a list-box input control is

```
LISTBOX ... [ , ... contents(conspec) ... ]
```

Wherever a `conspec` appears in a syntax diagram, you may type

```
list listname
```

populates the box with the specified list, which you create separately by using the LIST command. LIST has the following syntax:

```
LIST
    BEGIN
        item to appear
        item to appear
        ...
    END
```

```
matrix
```
populates the box with the names of all matrices currently defined in Stata.

```
vector
```
populates the box with the names of all $1 \times k$ and $k \times 1$ matrices currently defined in Stata.

```
row
```
populates the box with the names of all $1 \times k$ matrices currently defined in Stata.
column
    populates the box with the names of all \( k \times 1 \) matrices currently defined in Stata.

square
    populates the box with the names of all \( k \times k \) matrices currently defined in Stata.

scalar
    populates the box with the names of all scalars currently defined in Stata.

constraint
    populates the box with the names of all constraints currently defined in Stata.

estimates
    populates the box with the names of all saved estimates currently defined in Stata.

c\text{har } varname[\text{charname}]
    populates the box with the elements of the characteristic \text{varname}[\text{charname}], parsed on spaces.

e(name)
    populates the box with the elements of e(name), parsed on spaces.

global
    populates the box with the names of all global macros currently defined in Stata.

valuelabels
    populates the box with the names of all values labels currently defined in Stata.

Predefined lists for use with Stata graphics:

<table>
<thead>
<tr>
<th>Predefined lists</th>

<td>list of compass directions</td>
</tr>
<tr>
<td>yesno</td>
<td>list containing Default, Yes, and No; usually accompanied by a user-defined \text{values} list</td>
</tr>
</tbody>
</table>
2.4 Memory (recollection)

All input control commands have a `default()` or `contents()` option that specifies how the control is to be filled in, for example,

```
CHECKBOX ... [, ... default(defnumval) ... ]
```

In this command, if `defnumval` evaluates to 0, the checkbox is initially unchecked; otherwise, it is checked. If `default()` is not specified, the box is initially unchecked.

Dialogs remember how they were last filled in during a session, so the next time the user invokes the dialog box that contains this `CHECKBOX` command, the `default()` option will be ignored and the checkbox will be as the user last left it. That is, the setting will be remembered unless you specify the input control’s `nomemory` option.

```
CHECKBOX ... [, ... default(defnumval) nomemory ... ]
```

`nomemory` specifies that the dialog-box manager not remember between invocations how the control is filled in; it will always reset it to the default, whether that default is explicitly specified or implied.

Whether or not you specify `nomemory`, explicit or implicit defaults are also restored when the user presses the `Reset` helper button.

The contents of dialog boxes are only remembered during a session, not between them. Within a session, the `discard` command causes Stata to forget the contents of all dialog boxes.

The issues of initialization and memory are in fact more complicated than they first appear. Consider a list box. A list box might be populated with the currently saved estimates. If the dialog box containing this list box is closed and reopened, the available estimates may have changed. So list boxes are always repopulated according to the instructions given. Even so, list boxes remember the choice that was made. If that choice is still among the possibilities, that choice will be the one selected unless `nomemory` is specified; otherwise, the choice goes back to being the default—the first choice in the list of alternatives.

The same issues arise with combo boxes, and that is why some controls have the `default()` option and others have `contents()`. `default()` is used once, and after that, memory is substituted (unless `nomemory` is specified). `contents()` is always used—`nomemory` or not—but the choice made is remembered (unless `nomemory` is specified).

2.5 I-actions and member functions

I-actions—intermediate actions—refer to all actions taken in producing the u-action. An i-action might disable or hide controls when another control is checked or unchecked, although there are many other possibilities. I-actions are always optional.

I-actions are invoked by `on*()` options—those that begin with the letters “on”. For instance, the syntax for the `CHECKBOX` command—the command for defining a checkbox control—is

```
CHECKBOX controlname ... [, ... onclickon(iaction) onclickoff(iaction) ... ]
```

`onclickon()` is the i-action to be taken when the checkbox is checked, and `onclickoff()` is the i-action for when the checkbox is unchecked. You do not have to fill in the `onclickon()` and `onclickoff()` options—the checkbox will work fine taking no i-actions—but you may fill them in if you want, say, to disable or to enable other controls when this control is checked. For instance, you might code

```
CHECKBOX sw2 ..., onclickon(d2.sw3.show) onclickoff(d2.sw3.hide) ...
```
d2.sw3 refers to the control named sw3 in the dialog d2 (for instance, the control we just defined is named sw2). hide and show are called member functions. hide is the member function that hides a control, and show is its inverse. Controls have other member functions as well; what member functions are available is documented with the command that creates the specific control.

Many commands have on*() options that allow you to specify i-actions. When iaction appears in a syntax diagram, you can specify

. (period)

Do nothing; take no action. This is the default if you do not specify the on*() option.

gaction dialogname.controlname.memberfunction [arguments]

Execute the specified memberfunction on the specified control, where memberfunction may be

{ hide | show | disable | enable | setposition | something_else [arguments] }

All controls provide the memberfunctions hide, show, disable, enable, and setposition, and some controls make other, special memberfunctions available.

hide specifies that the control disappear from view (if it has not already done so). show specifies that it reappear (if it is not already visible).

disable specifies that the control be disabled (if it is not already). enable specifies that it be enabled (if it is not already).

setposition specifies the new position and size of a control. setposition requires arguments in the form of x y xsize ysize. A dot can be used with any of the four arguments to mean the current value.

Sometimes arguments may require quotes. For instance, CHECKBOX provides a special memberfunction

setlabel string

which sets the text shown next to the checkbox, so you might specify onclickon(’”gaction main.robust.setlabel ”Robust VCE””’). Anytime a string is required, you must place quotes around it if that string contains a space. When you specify an iaction inside the parentheses of an option, it is easier to leave the quotes off unless they are required. If quotes are required, you must enclose the entire contents of the option in compound double quotes as in the example above.

dialogname.controlname.memberfunction [arguments]

Same as gaction; the gaction is optional.

action memberfunction [arguments]

Same as gaction currentdialog.currentcontrol.memberfunction; executes the specified memberfunction on the current control.

view topic

Display topic in viewer; see [R] view.

script scriptname

Execute the specified script. A script is a set of lines, each specifying an iaction. So if you wanted to disable three things, gaction would be insufficient. You would instead define a script containing the three gaction lines.

program programname

Execute the specified dialog-box program. Programs can do more than scripts because they provide if-statement flow of control (among other things), but they are more difficult to write; typically, the extra capabilities are not needed when specifying i-actions.
create STRING | DOUBLE | BOOLEAN \textit{propertyname}

create PSTRING | PDOUBLE | PBOOLEAN \textit{propertyname}

create CHILD \textit{dialogname} [ \texttt{AS} \textit{referencename} ] [ , nomodal allowsubmit allowcopy ]

Creates a new instance of a child dialog. By default, the reference name will be the name of the dialog unless otherwise specified. See \textit{7. Child dialogs} for details.

\section{U-actions and communication options}

Remember that the ultimate goal of a dialog box is to construct a u-action—a Stata command to be executed. What that command is depends on how the user fills in the dialog box.

You construct the command by writing a dialog-box program, also known as a PROGRAM. You arrange that the program be invoked by specifying the \texttt{uaction()} option allowed with the \texttt{OK}, \texttt{SUBMIT}, \texttt{CANCEL}, and \texttt{COPY} u-action buttons. For instance, the syntax of \texttt{OK} is

\begin{verbatim}
OK ... [ , ... uaction(pgmname) target(target) ... ]
\end{verbatim}

\texttt{pgmname} is the name of the dialog program you write, and \texttt{target()} specifies how the command constructed by \texttt{pgmname} is to be executed. Usually, you will simply want Stata to execute the command, which could be coded \texttt{target(stata)}, but because that is the default, most programmers omit the \texttt{target()} option altogether.

The dialog-box program you write accesses the information the user has filled in and outputs the Stata command to be executed. Without going into details, the program might say to construct the command by outputting the word \texttt{regress}, followed by the \texttt{varlist} the user specified in the \texttt{varlist} field of the first dialog, and followed by \texttt{if exp}, getting the expression from what the user filled in an edit field of the second dialog.

Dialogs and input controls are named, and in your dialog-box program, when you want to refer to what a user has filled in, you refer to \textit{dialogname}.\textit{inputcontrolname}. \textit{dialogname} was determined when you coded the DIALOG command to create the dialog

\begin{verbatim}
DIALOG \textit{dialogname} ...
\end{verbatim}

and \textit{inputcontrolname} was determined when you coded the input-control command to create the input control, for instance,

\begin{verbatim}
CHECKBOX \textit{inputcontrolname} ...
\end{verbatim}

The details are discussed in \textit{5. PROGRAM}, but do not get lost in the details. Think first about coding how the dialogs look and second about how to translate what the user specifies into the u-action.

On the various commands that specify how dialogs look, you can specify an option that will make writing the u-action program easier: the communication option \texttt{option()}, which communicates something about the control to the u-action program, is allowed with every control. For instance, on the CHECKBOX command, you could code

\begin{verbatim}
CHECKBOX ... , ... option(robust) ... 
\end{verbatim}

When you wrote your dialog-box PROGRAM, you would find it easier to associate the \texttt{robust} option in the command you are constructing with this checkbox. Communication options never alter how a control looks or works: they just make extra information available to the PROGRAM and make writing the u-action routine easier.
Do not worry much about communication options when writing your dialog. Wait until you are writing the corresponding u-action program. Then it will be obvious what communication options you should have specified, and you can go back and specify them.

2.7 The distinction between i-actions and u-actions

In this documentation, we distinguish between i-actions and u-actions, but if you read carefully, you will realize that the distinction is more syntactical than real. One way we have distinguished i-actions from u-actions is to note that only u-actions can run Stata commands. In fact, i-actions can also run Stata commands; you just code them differently. In the vast majority of dialog boxes, you will not do this.

Nevertheless, if you were writing a dialog box to edit a Stata graph, you might construct your dialog box so that it contained no u-actions and only i-actions. Some of those i-actions might invoke Stata commands.

As you already know, i-actions can invoke PROGRAMs, and PROGRAMs serve two purposes: coding of i-actions and coding of u-actions. PROGRAMs themselves, however, have the ability to submit commands to Stata, and therein lies the key. I-actions can invoke PROGRAMs, and PROGRAMs can invoke Stata commands. How this is done is discussed in 5.1.3 rstrings: cmdstring and optstring and 5.5 Command-execution commands.

We recommend that you not program i-actions and u-actions that are virtually indistinguishable except in rare, special circumstances. Users expect to fill in a dialog box and to be given the opportunity to click on OK or Submit before anything too severe happens.

2.8 Error and consistency checking

In filling in the dialogs you construct, the user might make errors. One alternative is simply to ignore that possibility and let Stata complain when it executes the u-action command you construct. Even in well-written dialog boxes, most errors should be handled this way because discovering all the problems would require rewriting the entire logic of the Stata command.

Nevertheless, you will want to catch easy-to-detect errors while the dialog is still open and the user can easily fix them. Errors come in two forms: An outright error would be typing a number in an edit field that is supposed to contain a variable name. A consistency error would be checking two checkboxes that are, logically speaking, mutually exclusive.

You will want to handle most consistency errors at the dialog level, either by design (if two checkboxes are mutually exclusive, perhaps the information should be collected as radio buttons) or by i-actions (disabling or even hiding some fields depending on what has been filled in). The latter was discussed in 2.5 I-actions and member functions.

Outright errors can be detected and handled in dialog-box programs and are usually detected and handled in the u-action program. For instance, in your dialog-box program, you can assert that dialogname.inputcontrolname must be filled in and pop up a custom error message if it is not, or the program code can be written so that an automatically generated error message is presented. You will find that all input-control commands have an error() option; for example,

\[ \text{VARLIST} \ldots [ \ldots \text{error(string)} \ldots ] \]

The error() string provides the text to describe the control when the dialog-box manager presents an error. For instance, if we specified

\[ \text{VARLIST} \ldots [ \ldots \text{error(dependent variable)} \ldots ] \]
the dialog-box manager might use that information later to construct the error message “dependent variable must be specified”.

If you do not specify the \texttt{error()} option, the dialog-box manager will use what was specified in the \texttt{label()}; otherwise, "" is used. The \texttt{label()} option specifies the text that usually appears near the control describing it to the user, but \texttt{label()} will do double duty so that you only need to specify \texttt{error()} when the two strings need to differ.

3. Commands

3.1 VERSION

\textbf{Syntax}

\begin{verbatim}
VERSION #[ .## ] [ valid_operating_systems ]
\end{verbatim}

\textbf{Description}

\texttt{VERSION} specifies how the commands that follow are to be interpreted.

\textbf{Remarks}

\texttt{VERSION} must appear first in the .\texttt{dlg} file (it may be preceded by comments). In the current version of Stata, it should read \texttt{VERSION 15} or \texttt{VERSION 15.0}. It makes no difference; both mean the same thing.

Optionally, \texttt{VERSION} can specify one or more valid operating systems. Accepted values are \texttt{WINDOWS}, \texttt{MACINTOSH}, and \texttt{UNIX}. If none of these are specified, all are assumed.

Including \texttt{VERSION} at the top is of vital importance. Stata is under continual development, so syntax and features can change. Including \texttt{VERSION} is how you ensure that your dialog box will continue to work as you intended.

3.2 INCLUDE

\textbf{Syntax}

\begin{verbatim}
INCLUDE includefilename
\end{verbatim}

where \texttt{includefilename} refers to \texttt{includefilename.idlg} and must be specified without the suffix and without a path.

\textbf{Description}

\texttt{INCLUDE} reads and processes the lines from \texttt{includefilename.idlg} just as if they were part of the current file being read. \texttt{INCLUDE} may appear in both .\texttt{dlg} and .\texttt{idlg} files.

\textbf{Remarks}

The name of the file is specified without a file suffix and without a path. .\texttt{idlg} files are searched for along the ado-path, as are .\texttt{dlg} files.

\texttt{INCLUDE} may appear anywhere in the dialog code and may appear in both .\texttt{dlg} and .\texttt{idlg} files; include files may \texttt{INCLUDE} other include files. Files may contain multiple \texttt{INCLUDE}s. The maximum nesting depth is 10.
3.3 DEFINE

Syntax

```
DEFINE name { . | # | +# | -# | @x | @y | @xsize | @ysize }
```

Description

DEFINE creates `name`, which may be used in other commands wherever a position or size element is required.

Remarks

The first four possibilities for defining `name`—., #, +#, and #-specify default, number specified, positive offset, and negative offset.

The other four possibilities—@x, @y, @xsize, and @ysize—refer to the previous `x`, `y`, `xsize`, and `ysize` values, with “previous” meaning previous to the time the DEFINE command is issued, not at the time `name` is used.

3.4 POSITION

Syntax

```
POSITION x y xsize ysize
```

Description

POSITION is used to set the location and size of the dialog box. `x` and `y` refer to the upper-left-hand corner of the dialog box. `xsize` and `ysize` refer to the width and height of the dialog box.

Remarks

The positions `x` and `y` may each be specified as ., and Stata will determine where the dialog box will be displayed; this is recommended.

`xsize` and `ysize` may not be specified as . because they specify the overall size of the dialog box. You can discover the size by experimentation. If you specify a size that is too small, some elements will flow off the dialog box. If you specify a size that is too large, there will be large amounts of white space on the right and bottom of the dialog box. Good initial values for `xsize` and `ysize` are 400 and 300.

POSITION may be specified anywhere in the dialog code outside BEGIN ... END blocks. It does not matter where it is specified because the entire .dlg file is processed before the dialog box is displayed.
3.5 LIST

Syntax

```
LIST newlistname
BEGIN
  item
  item
  ...
END
```

Description

LIST creates a named list for populating list and combo boxes.

Example

```
LIST choices
BEGIN
  Statistics
  Graphics
  Data management
END
...
DIALOG ...
BEGIN
  ...
  LISTBOX ..., ..., contents(choices) ...
  ...
END
```

3.6 DIALOG

Syntax

```
DIALOG newdialogname [, title("string") tabtitle("string")]
BEGIN
  { control definition statements | INCLUDE | DEFINE }
  ...
END
```

Description

DIALOG defines a dialog. Every .dlg file should define at least one dialog. Only control definition statements, INCLUDE, and DEFINE are allowed between BEGIN and END.

Options

title("string") defines the text to be displayed in the dialog’s title bar.
tabtitle("string") defines the text to be displayed on the dialog’s tab. Dialogs are tabbed if more than one dialog is defined. When a user clicks on the tab, the dialog becomes visible and active. If only one dialog is specified, the contents of tabtitle() are irrelevant.
Member functions

```plaintext
settabtitle string  sets tab title to string
settitle string     sets overall dialog box title to string
```

`settitle` may be called as a member function of any dialog tab, but it is more appropriate to call it as a member function of the dialog box. This is accomplished by calling it in the local scope of the dialog.

Example:
```
settitle "sort - Sort data"
```

3.6.1 CHECKBOX on/off input control

Syntax

```plaintext
CHECKBOX newcontrolname x y xsize ysize [, label("string") error("string")
  default(defnumval) nomemory groupbox onclickon(iaction) onclickoff(iaction)
  option(optionname) tooltip("string") ]
```

Member functions

```plaintext
setlabel string     sets text to string
setoff              unchecks checkbox
seton               checks checkbox
setoption optionname associates optionname with the value of the checkbox
setdefault value    sets the default value for the checkbox; this does not change the selected state
settooltip string   sets the tooltip text to string
```

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.

Returned values for use in PROGRAM

Returns numeric, 0 or 1, depending on whether the box is checked.

Description

`CHECKBOX` defines a checkbox control, which indicates an option that is either on or off.

Options

`label("string")` specifies the text to be displayed next to the control. You should specify text that clearly implies two opposite states so that it is obvious what happens when the checkbox is checked or unchecked.

`error("string")` specifies the text to be displayed describing this field to the user in automatically generated error boxes.

`default(defnumval)` specifies whether the box is checked or unchecked initially; it will be unchecked if `defnumval` evaluates to 0, and it will be checked otherwise. If `default()` is not specified, `default(0)` is assumed.
nomemory specifies that the checkbox not remember how it was filled in between invocations.

groupbox makes this checkbox control also a group box into which other controls can be placed to emphasize that they are related. The group box is just an outline; it does not cause the controls “inside” to be disabled or hidden or in any other way act differently than they would if they were outside the group box. On some platforms, radio buttons have precedence over checkbox group boxes. You may place radio buttons within a checkbox group box, but do not place a checkbox group box within a group of radio buttons. If you do, you may not be able to click on the checkbox control on some platforms.

onclickon(iaction) and onclickoff(iaction) specify the i-actions to be invoked when the checkbox is clicked on or off. This could be used, for instance, to hide, show, disable, or enable other input controls. The default i-action is to do nothing. The onclickon() or onclickoff() i-action will be invoked the first time the checkbox is displayed.

option(optionname) is a communication option that associates optionname with the value of the checkbox.

tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

CHECKBOX robust 10 10 100 ., label(Robust VCE)

3.6.2 RADIO on/off input control

Syntax

RADIO newcontrolname x y xsize ysize [, [first|middle|last] label("string")
error("string") default(defnumval) nomemory onclickon(iaction)
onclickoff(iaction) option(optionname) tooltip("string")]

Member functions

setlabel string sets text to string
seton checks the radio button and unchecks any other buttons in the group
setoption optionname associates optionname with the value of the radio
setdefault value sets the default value for the radio; this does not change the selected state
settooltip string sets the tooltip text to string

The standard member functions hide, show, disable, enable, and setposition are also provided.

Returned values for use in PROGRAM

Returns numeric, 0 or 1, depending on whether the button is checked.
Description

RADIO defines a radio button control in a radio-button group. Radio buttons are used in groups of two or more to select mutually exclusive, but related, choices when the number of choices is small. Selecting one radio button automatically unselects the others in its group.

Options

first, middle, and last specify whether this radio button is the first, a middle, or the last member of a group. There must be one first and one last. There can be zero or more middle members. middle is the default if no option is specified.

label("string") specifies the text to be displayed next to the control.

error("string") specifies the text to be displayed describing this field to the user in automatically generated error boxes.

default(defnumval) specifies whether the radio button is to start as selected or unselected; it will be unselected if defnumval evaluates to 0 and will be selected otherwise. If default() is not specified, default(0) is assumed unless first is also specified, in which case default(1) is assumed. It is considered bad style to use anything other than the first button as the default, so this option is rarely specified.

nomemory specifies that the radio button not remember how it was filled in between invocations.

onclickon(iaction) and onclickoff(iaction) specify that i-action be invoked when the radio button is clicked on or clicked off. This could be used, for instance, to hide, show, disable, or enable other input controls. The default i-action is to do nothing. The onclickon() i-action will be invoked the first time the radio button is displayed if it is selected.

option(optionname) is a communication option that associates optionname with the value of the radio button.

tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

RADIO r1 10 10 100 ., first label("First choice")
RADIO r2 @ +20 @ ., middle label("Second choice")
RADIO r3 @ +20 @ ., middle label("Third choice")
RADIO r4 @ +20 @ ., last label("Last choice")

3.6.3 SPINNER numeric input control

Syntax

SPINNER newcontrolname x y xsize ysize [ , label("string") error("string")
    default(defnumval) nomemory min(defnumval) max(defnumval) onchange(iaction)
    option(optionname) tooltip("string") ]
Member functions

- `setvalue value` sets the actual value of the spinner to `value`
- `setrange min# max#` sets the range of the spinner to `min# max#`
- `setoption optionname` associates `optionname` with the value of the spinner
- `setdefault #` sets the default of the spinner to `#`; this does not change the value shown in the spinner control.
- `settooltip string` sets the tooltip text to `string`

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.

Returned values for use in PROGRAM

Returns numeric, the value of the spinner.

Description

`SPINNER` defines a spinner, which displays an edit field that accepts an integer number, which the user may either increase or decrease by clicking on an up or down arrow.

Options

- `label("string")` specifies a description for the control, but it does not display the label next to the spinner. If you want to label the spinner, you must use a `TEXT` static control.
- `error("string")` specifies the text to be displayed in describing this field to the user in automatically generated error boxes.
- `default(defnumval)` specifies the initial integer value of the spinner. If not specified, `min()` is assumed, and if that is not specified, 0 is assumed.
- `nomemory` specifies that the spinner not remember how it was filled in between invocations.
- `min(defnumval)` and `max(defnumval)` set the minimum and maximum integer values of the spinner. `min(0)` and `max(100)` are the defaults.
- `onchange(iaction)` specifies the i-action to be invoked when the spinner is changed. The default i-action is to do nothing. The `onchange()` i-action will be invoked the first time the spinner is displayed.
- `option(optionname)` is a communication option that associates `optionname` with the value of the spinner.
- `tooltip("string")` specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

```
SPINNER level 10 10 60 ., label(Sig. level) min(5) max(100) ///
   default(c(level)) option(level)
```
3.6.4 EDIT string input control

Syntax

```
EDIT newcontrolname x y xsize ysize [, label("string") error("string")
  default(defstrval) nomemory max(#) numonly password onchange(iaction)
  option(optionname) tooltip("string") ]
```

Member functions

- `setLabel string` sets the label for the edit field
- `setValue strvalue` sets the value shown in the edit field
- `append string` appends `string` to the value in the edit field
- `prepend string` prepends `string` to the value of the edit field
- `insert string` inserts `string` at the current cursor position of the edit field
- `smartInsert string` inserts `string` at the current cursor position in the edit field with leading and trailing spaces around it
- `setFocus` causes the control to obtain keyboard focus
- `setOption optionname` associates `optionname` with the contents of the edit field
- `setDefault string` sets the default value for the edit field; this does not change what is displayed
- `setTooltip string` sets the tooltip text to `string`

The standard member functions `hide`, `show`, `disable`, `enable`, and `setPosition` are also provided.

Returned values for use in PROGRAM

Returns `string`, the contents of the edit field.

Description

EDIT defines an edit field. An edit field is a box into which the user may enter text or in which the user may edit text; the width of the box does not limit how much text can be entered.

Options

- `label("string")` specifies a description for the control, but it does not display the label next to the edit field. If you want to label the edit field, you must use a TEXT static control.
- `error("string")` specifies the text to be displayed describing this field to the user in automatically generated error boxes.
- `default(defstrval)` specifies the default contents of the edit field. If not specified, `default("")` is assumed.
- `nomemory` specifies that the edit field is not to remember how it was filled in between invocations.
- `max(#)` specifies the maximum number of characters that may be entered into the edit field.
- `numonly` specifies that the edit field be able to contain only a period, numeric characters 0 through 9, and – (minus).
- `password` specifies that the characters entered into the edit field be shown on the screen as asterisks or bullets, depending on the operating system.
onchange(*i-action*) specifies the i-action to be invoked when the contents of the edit field are changed. The default i-action is to do nothing. Note that the onchange() i-action will be invoked the first time the edit field is displayed.

option(*optionname*) is a communication option that associates *optionname* with the contents of the edit field.

tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

**Example**

```plaintext
TEXT tlab 10 10 200 ., label("Title")
EDIT title @ +20 @ ., label("title")
```

### 3.6.5 VARLIST and VARNAME string input controls

**Syntax**

```plaintext
{ VARLIST | VARNAME } newcontrolname x y xsize ysize [ , label("string")
  error("string") default(defstrval) nomemory fv ts option(optionname)
  tooltip("string") ]
```

**Member functions**

- `setlabel string` sets the label for the varlist edit field
- `setvalue strvalue` sets the value shown in the varlist edit field
- `append string` appends *string* to the value in the varlist edit field
- `prepend string` prepends *string* to the value of the varlist edit field
- `insert string` inserts *string* at the current cursor position of the varlist edit field
- `smartinsert string` inserts *string* at the current cursor position in the varlist edit field with leading and trailing spaces around it
- `setfocus` causes the control to obtain keyboard focus
- `setoption optionname` associates *optionname* with the contents of the edit field
- `setdefault string` sets the default value for the edit field; this does not change what is displayed
- `settooltip string` sets the tooltip text to *string*

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.

**Returned values for use in PROGRAM**

Returns *string*, the contents of the varlist edit field.

**Description**

VARLIST and VARNAME are special cases of an edit field. VARLIST provides an edit field into which one or more Stata variable names may be entered (along with standard Stata varlist abbreviations), and VARNAME provides an edit field into which one Stata variable name may be entered (with standard Stata varname abbreviations allowed).
Options
label("string") specifies a description for the control, but does not display the label next to the varlist edit field. If you want to label the control, you must use a TEXT static control.
error("string") specifies the text to be displayed describing this field to the user in automatically generated error boxes.
default(defstrval) specifies the default contents of the edit field. If not specified, default("") is assumed.
nomem specifies that the edit field not remember how it was filled in between invocations.
fv specifies that the control add a factor-variable dialog button.
ts specifies that the control add a time-series-operated variable dialog button.
option(optionname) is a communication option that associates optionname with the contents of the edit field.
tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

```
TEXT dvlab 10 10 200 ., label("Dependent variable")
VARNAME depvar @ +20 @ ., label("dep. var")
TEXT ivlab @ +30 @ ., label("Independent variables")
VARLIST idepvars @ +20 @ ., label("ind. vars.")
```

3.6.6 FILE string input control

Syntax

```
FILE newcontrolname x y xsise ysize [, label("string") error("string")
   default(defstrval) nomem buttonwidth(#) dialogtitle(string) save
   multiselect directory filter(string) onchange(iaction) option(optionname)
   tooltip("string")]
```

Member functions

```
setlabel string     sets the label shown on the edit button
setvalue strvalue   sets the value shown in the edit field
append string       appends string to the value in the edit field
prepend string      prepends string to the value of the edit field
insert string       inserts string at the current cursor position of the edit field
smartinsert string  inserts string at the current cursor position in the edit field
   with leading and trailing spaces around it
setoption optionname associates optionname with the contents of the edit field
setdefault string   sets the default value for the edit field; this does not change
   what is displayed
settooltip string   sets the tooltip text to string
```

The standard member functions hide, show, disable, enable, and setposition are also provided.
Returned values for use in PROGRAM

Returns string, the contents of the edit field (the file chosen).

Description

FILE is a special edit field with a button on the right for selecting a filename. When the user clicks on the button, a file dialog is displayed. If the user selects a filename and clicks on OK, that filename is put into the edit field. The user may alternatively type a filename into the edit field.

Options

label("string") specifies the text to appear on the button. The default is ("Browse ...").
error("string") specifies the text to be displayed describing this field to the user in automatically generated error boxes.
default(defstrval) specifies the default contents of the edit field. If not specified, default("") is assumed.
nomemory specifies that the edit field not remember how it was filled in between invocations.
buttonwidth(#) specifies the width in pixels of the button. The default is buttonwidth(80). The overall size specified in xsise includes the button.
dialogtitle(string) is the title to show on the file dialog when you click on the file button.
save specifies that the file dialog allow the user to choose a filename for saving rather than one for opening.
multiselect specifies that the file dialog allow the user to select multiple filenames rather than only one filename.
directory specifies that the file dialog select a directory rather than a filename. If specified, any nonrelevant options will be ignored.
filter(string) consists of pairs of descriptions and wildcard file selection strings separated by "|", such as

    filter("Stata Graphs|*.gph|All Files|*.*")
onchange(iaction) specifies an i-action to be invoked when the user changes the chosen file. The default i-action is to do nothing. The onchange() i-action will be invoked the first time the file chooser is displayed.
option(optionname) is a communication option that associates optionname with the contents of the edit field.
tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

    FILE fname 10 10 300 ., error("Filename to open") label("Browse ...")
3.6.7 LISTBOX list input control

Syntax

LISTBOX newcontrolname x y xsize ysize [, label("string") error("string")]
nomemory contents(conspc) values(listname) default(defstrval)
ondblclick(iaction) [ onselchange(iaction) | onselchangelist(listname) ]
option(optionname) tooltip("string")]

Member functions

setlabel string sets the label for the list box
setvalue strvalue sets the currently selected item
setfocus causes the control to obtain keyboard focus
setoption optionname associates optionname with the element chosen from the list
setdefault string sets the default value for the list box; this does not change what is displayed
repopulate causes the associated contents list to rebuild itself and then updates the control with the new values from that list
forceselchange forces an onselchange event to occur
settooltip string sets the tooltip text to string

The standard member functions hide, show, disable, enable, and setposition are also provided.

Returned values for use in PROGRAM

Returns string, the text of the item chosen, or, if values(listname) is specified, the text from the corresponding element of listname.

Description

LISTBOX defines a list box control. Like radio buttons, a list box allows the user to make a selection from a number of mutually exclusive, but related, choices. A list box control is more appropriate when the number of choices is large.

Options

label("string") specifies a description for the control but does not display the label next to the control. If you want to label the list box, you must use a TEXT static control.

error("string") specifies the text to be displayed describing this field to the user in automatically generated error boxes.

nomemory specifies that the list box not remember the item selected between invocations.

contents(conspc) specifies the items to be shown in the list box. If contents() is not specified, the list box will be empty.

values(listname) specifies the list (see 3.5 LIST) for which the values of contents() should match one to one. When the user chooses the kth element from contents(), the kth element of listname will be returned. If the lists do not match one to one, extra elements of listname are ignored, and extra elements of contents() return themselves.
default(defstrval) specifies the default selection. If not specified, or if defstrval does not exist, the first item is the default.

ondblclick(iaction) specifies the i-action to be invoked when an item in the list is double clicked. The double-clicked item is selected before the iaction is invoked.

onselchange(iaction) and onselchangelist(listname) are alternatives. They specify the i-action to be invoked when a selection in the list changes.

onselchange(iaction) performs the same i-action, regardless of which element of the list was chosen.

onselchangelist(listname) specifies a vector of iactions that should match one to one with contents(). If the user selects the kth element of contents(), the kth i-action from listname is invoked. See 3.5 LIST for information on creating listname. If the elements of listname do not match one to one with the elements of contents(), extra elements are ignored, and if there are too few elements, the last element will be invoked for the extra elements of contents().

option(optionname) is a communication option that associates optionname with the element chosen from the list.

tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

```
LIST ourlist
BEGIN
    Good
    Common or average
    Poor
END
.
.
DIALOG . . .
BEGIN
    . . .
    TEXT ourlab 10 10 200 ., label("Pick a rating")
    LISTBOX rating @ +20 150 200, contents(ourlist)
    . . .
END
```

3.6.8 COMBOBOX list input control

Syntax

```
COMBOBOX newcontrolname x y xsize ysize [, label("string") error("string")]
    [regular|dropdown|dropdownlist] default(defstrval) nomemory
    contents(conspec) values(listname) append
    [ onselchange(iaction) | onselchangelist(listname) ] option(optionname)
    tooltip("string") ]
```
**Member functions**

- **setlabel string**
  sets the label for the combo box

- **setvalue strvalue**
  in the case of regular and drop-down combo boxes, sets the value of the edit field; in the case of a dropdownlist, sets the currently selected item.

- **setfocus**
  causes the control to obtain keyboard focus

- **setoption optionname**
  associates optionname with the element chosen from the list

- **setdefault string**
  sets the default value for the combo box; this does not change what is displayed or selected

- **repopulate**
  causes the associated contents list to rebuild itself and then updates the control with the new values from that list

- **forceselchange**
  forces an onselchange event to occur

- **settooltip string**
  sets the tooltip text to string

Also, except for drop-down lists (option dropdownlist specified), the following member functions are also available:

- **append string**
  appends string to the value in the edit field

- **prepend string**
  prepends string to the value of the edit field

- **insert string**
  inserts string at the current cursor position of the edit field

- **smartinsert string**
  inserts string at the current cursor position in the edit field with leading and trailing spaces around it

The standard member functions hide, show, disable, enable, and setposition are also always provided.

**Returned values for use in PROGRAM**

Returns string, the contents of the edit field.

**Description**

COMBOBOX defines regular combo boxes, drop-down combo boxes, and drop-down-list combo boxes. By default, COMBOBOX creates a regular combo box; it creates a drop-down combo box if the dropdown option is specified, and it creates a drop-down-list combo box if the dropdownlist option is specified.

A regular combo box contains an edit field and a visible list box. The user may make a selection from the list box, which is entered into the edit field, or type in the edit field. Multiple selections are allowed using the append option. Regular combo boxes are useful for allowing multiple selections from the list as well as for allowing the user to type in an item not in the list.

A drop-down combo box contains an edit field and a list box that appears when the control is clicked on. The user may make a selection from the list box, which is entered into the edit field, or type in the edit field. The control has the same functionality and options as a regular combo box but requires less space. Multiple selections are allowed using the append option. Drop-down combo boxes may be cumbersome to use if the number of choices is large, so use them only when the number of choices is small or when space is limited.

A drop-down-list combo box contains a list box that displays only the current selection. Clicking on the control displays the entire list box, allowing the user to make a selection without typing in the edit field; the user chooses among the given alternatives. Drop-down-list combo boxes should be used only when the number of choices is small or when space is limited.
Options

label("string") specifies a description for the control but does not display the label next to the combo box. If you want to label a combo box, you must use a TEXT static control.

error("string") specifies the text to be displayed describing this field to the user in automatically generated error boxes.

regular, dropdown, and dropdownlist specify the type of combo box to be created.

If regular is specified, a regular combo box is created. regular is the default.

If dropdown is specified, a drop-down combo box is created.

If dropdownlist is specified, a drop-down-list combo box is created.

default(defstrval) specifies the default contents of the edit field. If not specified, default("" ) is assumed. If dropdownlist is specified, the first item is the default.

nomemory specifies that the combo box not remember the item selected between invocations. Even for drop-down lists—where there is no default()—combo boxes remember previous selections by default.

contents(conspec) specifies the items to be shown in the list box from which the user may choose. If contents() is not specified, the list box will be empty.

values(listname) specifies the list (see 3.5 LIST) for which the values of contents() should match one to one. When the user chooses the kth element from contents(), the kth element of listname is copied into the edit field. If the lists do not match one to one, extra elements of listname are ignored, and extra elements of contents() return themselves.

append specifies that selections made from the combo box’s list box be appended to the contents of the combo box’s edit field. By default, selections replace the contents of the edit field. append is not allowed if dropdownlist is also specified.

onselchange(iaction) and onselchangelist(listname) are alternatives that specify the i-action to be invoked when a selection in the list changes.

onselchange(iaction) performs the same i-action, regardless of the element of the list that was chosen.

onselchangelist(listname) specifies a vector of iactions that should match one to one with contents(). If the user selects the kth element of contents(), the kth i-action from listname is invoked. See 3.5 LIST for information on creating listname. If the elements of listname do not match one to one with the elements of contents(), extra elements are ignored, and if there are too few elements, the last element will be invoked for the extra elements of contents(). onselchangelist() should not be specified with dropdown.

option(optionname) is a communication option that associates optionname with the element chosen from the list.

tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.
Example

```plaintext
LIST namelist
    BEGIN
        John
        Sue
        Frank
    END

DIALOG . . .
    BEGIN
        TEXT ourlab 10 10 200 ., label("Pick one or more names")
        COMBOBOX names @ +20 150 200, contents(namelist) append
    END
```

3.6.9 BUTTON special input control

**Syntax**

```plaintext
BUTTON newcontrolname x y xsize ysize [, label("string") error("string")
    onpush(iaction) tooltip("string")]
```

**Member functions**

- `setlabel string` sets the label for the button
- `setfocus` causes the control to obtain keyboard focus
- `settooltip string` sets the tooltip text to `string`

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.

**Returned values for use in PROGRAM**

None.

**Description**

`BUTTON` creates a push button that performs instantaneous actions. Push buttons do not indicate a state, such as on or off, and do not return anything for use by the u-action `PROGRAM`. Buttons are used to invoke i-actions.

**Options**

- `label("string")` specifies the text to display on the button. You should specify text that contains verbs that describe the action to perform.
- `error("string")` specifies the text to be displayed describing this field to the user in automatically generated error boxes.
- `onpush(iaction)` specifies the i-action to be invoked when the button is clicked on. If `onpush()` is not specified, the button does nothing.
tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

**Example**

```
BUTTON help 10 10 80 ., label("Help") onpush("view help example")
```

### 3.6.10 TEXT static control

**Syntax**

```
TEXT newcontrolname x y xsize ysize [, label("string") [left|center|right]]
```

**Member functions**

- `setlabel string` sets the text shown

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.

**Returned values for use in PROGRAM**

None.

**Description**

TEXT displays text.

**Options**

- `label("string")` specifies the text to be shown.
- `left`, `center`, and `right` are alternatives that specify the horizontal alignment of the text with respect to `x`. `left` is the default.

**Example**

```
TEXT dvlab 10 10 200 ., label("Dependent variable")
```

### 3.6.11 TEXTBOX static control

**Syntax**

```
TEXTBOX newcontrolname x y xsize ysize [, label("string") [left|center|right]]
```

**Member functions**

- `setlabel string` sets the text shown

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.
Returned values for use in PROGRAM

None.

Description

TEXTBOX displays multiline text.

Options

label("string") specifies the text to be shown.

left, center, and right are alternatives that specify the horizontal alignment of the text with respect to x. left is the default.

Example

TEXT tx_note 10 10 200 45, label("Note ...")

3.6.12 GROUPBOX static control

Syntax

GROUPBOX newcontrolname x y xsize ysize [, label("string")]

Member functions

setLabel string sets the text shown above the group box

The standard member functions hide, show, disable, enable, and setposition are also provided.

Returned values for use in PROGRAM

None.

Description

GROUPBOX displays a frame (an outline) with text displayed above it. Group boxes are used for grouping related controls together. The grouped controls are sometimes said to be inside the group box, but there is no meaning to that other than the visual effect.

Options

label("string") specifies the text to be shown at the top of the group box.

Example

GROUPBOX weights 10 10 300 200, label("Weight type")
  RADIO w1 . . . , . . . label(fweight) first . . .
  RADIO w2 . . . , . . . label(aweight) . . .
  RADIO w3 . . . , . . . label(pweight) . . .
  RADIO w4 . . . , . . . label(iweight) last . . .
3.6.13 FRAME static control

Syntax

FRAME newcontrolname x y xsise ysize [ , label("string") ]

Member functions

There are no special member functions provided.

The standard member functions hide, show, disable, enable, and setposition are also provided.

Returned values for use in PROGRAM

None.

Description

FRAME displays a frame (an outline).

Options

label("string") specifies the label for the frame, which is not used in any way, but some programmers use it to record comments documenting the purpose of the frame.

Remarks

The distinction between a frame and a group box with no label is that a frame draws its outline using the entire dimensions of the control. A group box draws its outline a few pixels offset from the top of the control, whether there is a label or not. A frame is useful for horizontal alignment with other controls.

Example

FRAME box 10 10 300 200
   RADIO w1 . . . , . . . label(fweight) first . . .
   RADIO w2 . . . , . . . label(aweight) . . .
   RADIO w3 . . . , . . . label(pweight) . . .
   RADIO w4 . . . , . . . label(iweight) last . . .

3.6.14 COLOR input control

Syntax

COLOR newcontrolname x y xsise ysize [ , label("string") error("string")
   default(rgbvalue) nomemory onchange(iaction) option(optionname)
   tooltip("string") ]
Member functions

```plaintext
setvalue rgbvalue  sets the rgb value of the color selector
setoption optionname associates optionname with the selected color
setdefault rgbvalue sets the default rgb value of the color selector; this does not change the selected color
settooltip string sets the tooltip text to string
```

The standard member functions hide, show, disable, enable, and setposition are also provided.

Returned values for use in PROGRAM

Returns rgbvalue of the selected color as a string.

Description

COLOR defines a button to access a color selector. The button shows the color that is currently selected.

Options

- `label("string")` specifies a description for the control, but it does not display the label next to the button. If you want to label the color control, you must use a TEXT static control.
- `error("string")` specifies the text to be displayed describing this field to the user in automatically generated error boxes.
- `default(rgbvalue)` specifies the default color of the color control. If not specified, `default(255 0 0)` is assumed.
- `nomemory` specifies that the color control not remember the set color between invocations.
- `onchange(iaction)` specifies the i-action to be invoked when the color is changed. The default i-action is to do nothing. Note that the `onchange()` i-action will be invoked the first time the color control is displayed.
- `option(optionname)` is a communication option that associates optionname with the selected color.
- `tooltip("string")` specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

```plaintext
COLOR box_color 10 10 40 ., default(0 0 0)
```

3.6.15 EXP expression input control

Syntax

```plaintext
EXP newcontrolname x y xsize ysize [, label("string") error("string")
default(defstrval) nomemory onchange(iaction) option(optionname)
tooltip("string")]
```
Member functions

- **setLabel** `string` sets the label for the button
- **setValue** `strvalue` sets the value shown in the edit field
- **append** `string` appends `string` to the value in the edit field
- **prepend** `string` prepends `string` to the value of the edit field
- **insert** `string` inserts `string` at the current cursor position of the edit field
- **smartInsert** `string` inserts `string` at the current cursor position in the edit field with leading and trailing spaces around it
- **setOption** `optionname` associates `optionname` with the contents of the edit field
- **setDefault** `string` sets the default value for the edit field; this does not change what is displayed
- **setTooltip** `string` sets the tooltip text to `string`

The standard member functions `hide`, `show`, `disable`, `enable`, and `setPosition` are also provided.

Returned values for use in PROGRAM

Returns `string`, the contents of the edit field.

Description

`EXP` defines an expression control that consists of an edit field and a button for launching the Expression Builder.

Options

- **label("string")** specifies the text for labeling the button.
- **error("string")** specifies the text to be displayed describing this field to the user in automatically generated error boxes.
- **default(defstrval)** specifies the default contents of the edit field. If not specified, `default("")` is assumed.
- **nomemory** specifies that the edit field not remember how it was filled in between invocations.
- **onChange(iaction)** specifies the i-action to be invoked when the contents of the edit field are changed. The default i-action is to do nothing. Note that the `onChange()` i-action will be invoked the first time the expression control is displayed.
- **option(optionname)** is a communication option that associates `optionname` with the contents of the edit field.
- **tooltip("string")** specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Example

```
TEXT tlab 10 10 200 ., label("Expression:")
EXP exp 0 +20 0 ., label("Expression")
```
3.6.16 HLINK hyperlink input control

Syntax

```c
HLINK newcontrolname x y xsize ysize [, label("string") [left|center|right]
onpush(iaction)]
```

Member functions

- `setlabel string`: sets the text shown

The standard member functions `hide`, `show`, `disable`, `enable`, and `setPosition` are also provided.

Returned values for use in PROGRAM

None.

Description

`HLINK` creates a hyperlink that performs instantaneous actions. Hyperlinks do not indicate a state, such as on or off, and do not return anything for use by the u-action `PROGRAM`. Hyperlinks are used to invoke i-actions.

Options

- `label("string")`: specifies the text to be shown.
- `left`, `center`, and `right` are alternatives that specify the horizontal alignment of the text with respect to `x`. `left` is the default.
- `onpush(iaction)`: specifies the i-action to be invoked when the hyperlink is clicked on. If `onpush()` is not specified, the hyperlink does nothing.

Example

```c
HLINK help 10 10 80 ., label("Help") onpush("view help example")
```

3.6.17 TREEVIEW tree input control

Syntax

```c
TREEVIEW newcontrolname x y xsize ysize [, label("string") error("string")
nomemory contents(conspec) values(listname) default(defstrval)
ondblclick(iaction) [ onselchange(iaction) | onselchangelist(listname)
option(optionname) tooltip("string")]
```

**Member functions**

- `setlabel string` sets the label for the tree
- `setvalue strvalue` sets the currently selected item
- `setfocus` causes the control to obtain keyboard focus
- `setoption optionname` associates `optionname` with the element chosen from the tree
- `setdefault string` sets the default value for the tree; this does not change what is displayed
- `forceselchange string` forces an `onselchange` event to occur
- `settooltip string` sets the tooltip text to `string`

The standard member functions `hide`, `show`, `disable`, `enable`, and `setposition` are also provided.

**Returned values for use in PROGRAM**

Returns `string`, the text of the item chosen, or, if `values(listname)` is specified, the text from the corresponding element of `listname`.

**Description**

`TREEVIEW` defines a tree control, which is used to display a hierarchical view of labeled items. A tree view allows the user to select from several mutually exclusive but related choices. By clicking on an item, the user can expand or collapse the associated list of subitems.

**Options**

- `label("string")` specifies a description for the control but does not display the label next to the control. If you want to label a tree view, you must use a `TEXT` static control.
- `error("string")` specifies the text to be displayed describing this field to the user in automatically generated error boxes.
- `nomemory` specifies that the control not remember the item selected between invocations.
- `contents(conspec)` specifies the items to be shown in the control. If `contents()` is not specified, the tree view control will be empty.
- `values(listname)` specifies the list (see 3.5 LIST) for which the values of `contents()` should match one to one. When the user chooses the `k`th element from `contents()`, the `k`th element of `listname` will be returned. If the lists do not match one to one, extra elements of `listname` are ignored, and extra elements of `contents()` return themselves.
- `default(defstrval)` specifies the default selection. If not specified, or if `defstrval` does not exist, the first item is the default.
- `ondblclick(iaction)` specifies the i-action to be invoked when an item in the control is double clicked. The double-clicked item is selected before the `iaction` is invoked.
- `onselchange(iaction)` and `onselchangelist(listname)` are alternatives. They specify the i-action to be invoked when a selection in the control changes.
- `onselchange(iaction)` performs the same i-action, regardless of which element of the control was chosen.
- `onselchangelist(listname)` specifies a vector of `iactions` that should match one to one with `contents()`. If the user selects the `k`th element of `contents()`, the `k`th i-action from `listname` is invoked. See 3.5 LIST for information on creating `listname`. If the elements of `listname` do not match one to one with the elements of `contents()`, extra elements are ignored, and if there are too few elements, the last element will be invoked for the extra elements of `contents()`.
option(optionname) is a communication option that associates optionname with the element chosen from the tree view control.

tooltip("string") specifies the text to be displayed as a tip or hint when the user hovers over the control with the mouse.

Organize data

TREEVIEW represents a hierarchical view of information where each item may have a number of subitems. Items (nodes) in the tree view can be expanded or collapsed to show or hide subitems. For example,

```
Root 1
  SubItem A
    SubItem A1
    SubItem A2
  SubItem B
Root 2
  SubItem C
```

The parent–child relationship data are stored in a content list. Each item in the list represents a node of the tree. The string labeling each item contains two parts. The first part encloses a nonnegative integer in square brackets to denote the level or depth of each node. The second part following the square brackets is the content shown in the tree.

Example

```
LIST ourcontentlist
BEGIN
  [0]Root 1
  [1]SubItem A
  [2]SubItem A1
  [2]SubItem A2
  [1]SubItem B
  [0]Root 2
  [1]SubItem C
END

DIALOG . .
BEGIN
  . .
  TEXT ourlab 10 10 200 ., label("Pick an item")
  TREEVIEW ourtree @ +20 150 200, contents(ourcontentlist)
  . .
END
```

3.7 OK, SUBMIT, CANCEL, and COPY u-action buttons

Syntax

```
{ OK | SUBMIT | COPY } newbuttonname [ , label("string") uaction(programname) target(target) ]

CANCEL newbuttonname [ , label("string") ]
```
Description

OK, CANCEL, SUBMIT, and COPY define buttons that, when clicked on, invoke a u-action. At least one of the buttons should be defined (or the dialog will have no associated u-action); only one of each button may be defined; and usually, good style dictates defining all four.

OK executes `programname`, removes the dialog box from the screen, and submits the resulting command produced by `programname` to `target`. If no other buttons are defined, clicking on the close icon of the dialog box does the same thing.

SUBMIT executes `programname`, leaves the dialog box on the screen, and submits the resulting command produced by `programname` to `target`.

CANCEL removes the dialog from the screen and does nothing. If this button is defined, clicking on the close icon of the dialog box does the same thing.

COPY executes `programname`, leaves the dialog box on the screen, and copies the resulting command produced by `programname` to `target`. By default, the `target` is the `clipboard`.

You do not specify the location or size of these controls. They will be placed in the dialog box where the user would expect to see them.

Options

`label("string")` defines the text to appear on the button. The default `label()` is OK, Submit, and Cancel for each individual button.

`uaction(programname)` specifies the PROGRAM to be executed. `uaction(command)` is the default.

`target(target)` defines what is to be done with the resulting string (command) produced by `programname`. The alternatives are

- `target(stata)`: The command is to be executed by Stata. This is the default.
- `target(stata hidden)`: The command is to be executed by Stata, but the command itself is not to appear in the Results window. The output from the command will appear normally. **This option may change in the future and should be avoided when possible.**
- `target(cmdwin)`: The command is to be placed in the Command window so that the user can edit it and then press `Enter` to submit it.
- `target(clipboard)`: The command is to be placed on the clipboard so that the user can paste it into the desired editor.

Example

```
OK ok1
CANCEL can1
SUBMIT sub1
COPY copy1
```

3.8 HELP and RESET helper buttons

Syntax

```
HELP newbuttonname [, view("viewertopic")]

RESET newbuttonname
```
Dialog Programming

Description

HELP defines a button that, when clicked on, presents viewertopic in the Viewer. viewertopic is typically specified as "view helpfile".

RESET defines a button that, when clicked on, resets the values of the controls in the dialog box to their initial state, just as if the dialog box were invoked for the first time. Each time a user invokes a dialog box, its controls will be filled in with the values the user last entered. RESET restores the control values to their defaults.

You do not specify the location, size, or appearance of these controls. They will be placed in the lower-left corner of the dialog box. The HELP button will have a question mark on it, and the RESET button will have an R on it.

Option

view("viewertopic") specifies the topic to appear in the Viewer when the user clicks on the button.

The default is view("help contents").

Example

HELP hlp1, view("help mycommand")
RESET res1

3.9 Special Dialog Directives

Syntax

\{ MODAL | SYNCHRONOUS_ONLY \}

Description

MODAL instructs the dialog to have modal behavior.

SYNCHRONOUS_ONLY allows the dialog to invoke stata hidden immediate at special times during the initialization process. See 5.5.1 stata for more information on this topic.

4. SCRIPT

Syntax

SCRIPT newscriptname
BEGIN
iaction
. . .
END
where iaction is

. action memberfunction
gaction dialogname.controlname.memberfunction
dialogname.controlname.memberfunction

script scriptname

view topic

program programname

See [2.5 I-actions and member functions](#) for more information on iactions.

### Description

SCRIPT defines the newscriptname, which in turn defines a compound i-action. I-actions are invoked by the on *() options of the input controls. When a script is invoked, the lines are executed sequentially, and any errors are ignored.

### Remarks

CHECKBOX provides onclickon(iaction) and onclickoff(iaction) options. Let’s focus on the onclickon(iaction) option. If you wanted to take just one action when the box was checked—say, disabling d1.sw2—you could code

```dialog
CHECKBOX . . ., . . . onclickon(d1.s2.disable) . . .
```

If you wanted to take two actions, say, disabling d1.s3 as well, you would have to use a SCRIPT. On the CHECKBOX command, you would code

```dialog
CHECKBOX . . ., . . . onclickon(script buttonsoff) . . .
```

and then somewhere else in the .dlg file (it does not matter where), you would code

```dialog
SCRIPT buttonsoff
BEGIN
  d1.s2.disable
  d1.s3.disable
END
```

### 5. PROGRAM

#### Syntax

```dialog
PROGRAM programname
BEGIN
  [ program_line | INCLUDE ]
  [ . . . ]
END
```

#### Description

PROGRAM defines a dialog program. Dialog programs are used to describe complicated i-actions and to implement u-actions.
Remarks

Dialog programs are used to describe complicated i-actions when flow control (if/then) is necessary or when you wish to create heavyweight i-actions that are like u-actions because they invoke Stata commands; otherwise, you should use a SCRIPT. Used this way, programs are invoked when the specified iaction is program programname in an on*() option of an input control command; for instance, you could code

```stata
CHECKBOX . . . , . . . onclickon(program complicated) . . .
```
or use a SCRIPT:

```stata
CHECKBOX . . . , . . . onclickon(script multi) . . .
```

```stata
    SCRIPT multi
    BEGIN
    . . .
    program complicated
    . . .
    END
```

The primary use of dialog programs, however, is to implement u-actions. The program constructs and returns a string, which the dialog-box manager will then interpret as a Stata command. The program is invoked by the uaction() options of OK and SUBMIT; for instance,

```stata
OK . . . , . . . uaction(program command) . . .
```

The u-action program is nearly always named command because, if the uaction() option is not specified, command is assumed. The u-action program may, however, be named as you please.

Here is an example of a dialog program being used to implement an i-action with if/then flow control:

```stata
PROGRAM testprog
    BEGIN
    if sample.cb1 & sample.cb2 {
        call sample.txt1.disable
    }
    if !(sample.cb1 & sample.cb2) {
        call sample.txt1.enable
    }
    END
```

Here is an example of a dialog program being used to implement the u-action:

```stata
PROGRAM command
    BEGIN
    put "mycmd "
    varlist main.vars // varlist [main.vars] would make optional
    ifexp main.if
    inrange main.obs1 main.obs2
    beginoptions
    option options.detail
    optionarg options.title
    endoptions
    END
```

Using programs to implement heavyweight i-actions is much like implementing u-actions, except the program might not be a function of the input controls, and you must explicitly code the stata command to execute what is constructed. Here is an example of a dialog program being used to implement a heavyweight i-action:
5.1 Concepts

5.1.1 Vnames

Vname stands for value name and refers to the “value” of a control. Vnames are of the form `dialogname.controlname`; for example, `d2.s2` and `d2.list` would be vnames if input controls `s2` and `list` were defined in `DIALOG d2`:

```
DIALOG d2 . . .
BEGIN
  . . .
  CHECKBOX s2 . . .
  EDIT list . . .
  . . .
END
```

A vname can be numeric or string depending on the control to which it corresponds. For CHECKBOX, it was documented under “Returned value for use in PROGRAM” that CHECKBOX “returns numeric, 0 or 1, depending on whether box is checked”, so `d2.s2` is a numeric. For the EDIT input control, it was documented that EDIT returns a string representing the contents of the edit field, so `d2.list` is a string.

Different words are sometimes used to describe whether vname is numeric or string, including:

- `vname` is numeric
- `vname` is string
- `vname` is a numeric control
- `vname` is a string control
- `vname` returns a numeric result
- `vname` returns a string result

In a program, you may not assign values to vnames; you may only examine their values and, for u-action (and heavyweight i-action) programs, output them. Thus dialog programs are pretty relaxed about types. You can ask whether `d2.s2` is true or `d2.list` is true, even though `d2.list` is a string. For a string, it is true if it is not "". Numeric vnames are true if the numeric result is not 0.

5.1.2 Enames

Enames are an extension of vnames. An ename is defined as

- `vname`
- `or(vname vname . . . vname)`
- `radio(dialogname controlname . . . controlname)`
or() returns the *vname* of the first in the list that is true (filled in). For instance, the varlist u-action dialog-programming command “outputs” a varlist (see 5.1.3 rstrings: cmdstring and optstring). If you knew that the varlist was in either control `d1.field1` or `d1.field2` and knew that both could not be filled in, you might code

```plaintext
varlist or(d1.field1 d1.field2)
```

which would have the same effect as

```plaintext
if d1.field1 {
    varlist d1.field1
}
if (!d1.field1) & d2.field2 {
    varlist d2.field2
}
```

`radio()` is for dealing with radio buttons. Remember that each radio button is a separate control, and yet, in the set, we know that exactly one is clicked on. `radio` finds the clicked one. Typing

```plaintext
option radio(d1 b1 b2 b3 b4)
```

would be equivalent to typing

```plaintext
option or(d1.b1 d1.b2 d1.b3 d1.b4)
```

which would be equivalent to typing

```plaintext
option d1.b2
```

assuming that the second radio button is selected. (The `option` command outputs the option corresponding to a control.)

### 5.1.3 rstrings: cmdstring and optstring

Rstrings, `cmdstring` and `optstring`, are relevant only in u-action and heavyweight i-action programs.

The purpose of a u-action program is to build and return a string, which Stata will ultimately execute. To do that, dialog programs have an *rstring* to which the dialog-programming commands implicitly contribute. For example,

```plaintext
put "kappa"
```

would add “kappa” (without the quotes) to the end of the rstring currently under construction, known as the current rstring. Usually, the current rstring is `cmdstring`, but within a `beginoptions/endoptions` block, the current rstring is switched to `optstring`:

```plaintext
beginoptions
put "kappa"
endoptions
```

The above would add “kappa” (without the quotes) to `optstring`.

When the program concludes, the `cmdstring` and the `optstring` are put together—separated by a comma—and that is the command Stata will execute. In any case, any command that can be used outside `beginoptions/endoptions` can be used inside them, and the only difference is the rstring to which the output is directed. Thus if our entire u-action program read
PROGRAM command
BEGIN
  put "kappa"
beginoptions
  put "kappa"
endoptions
END

the result would be to execute the command “kappa, kappa”.

The difference between a u-action program and a heavyweight i-action program is that you must, in your program, specify that the constructed command be executed. You do this with the stata command. The stata command can also be used in u-action programs if you wish to execute more than one Stata command:

PROGRAM command
BEGIN
  put, etc. // construct first command
  stata // execute first command
  clear // clear cmdstring and optstring
  put, etc. // construct second command
  // execution will be automatic
END

5.1.4 Adding to an rstring

When adding to an rstring, be aware of some rules in using spaces. Call A the rstring and B the string being added (say “kappa”). The following rules apply:

1. If A does not end in a space and B does not begin with a space, the two strings are joined to form “AB”. If A is “this” and B is “that”, the result is “thisthat”.

2. If A ends in one or more spaces and B does not begin with a space, the spaces at the end of A are removed, one space is added, and B is joined to form “rightstrip(A) B”. If A is “this ” and B is “that”, the result is “this that”.

3. If A does not end in a space and B begins with one or more spaces, the spaces at the beginning of B are ignored and treated as if there is one space, and the two strings are joined to form “A leftstrip(B)”. If A is “this” and B is “ that”, the result is “this that”.

4. If A ends in one or more spaces and B begins with one or more spaces, the spaces at the end of A are removed, the spaces at the beginning of B are ignored, and the two strings are joined with one space in between to form “rightstrip(A) leftstrip(B)”. If A is “this ” and B is “ that”, the result is “this that”.

These rules ensure that multiple spaces do not end up in the resulting string so that the string will look better and more like what a user might have typed.

When string literals are put, they are nearly always put with a trailing space

put "kappa 

to ensure that they do not join up with whatever is put next. If what is put next has a leading space, that space will be ignored.
5.2 Flow-control commands

5.2.1 if

Syntax

```
if ifexp {
    ...
}
or
if ifexp {
    ...
} else {
    ...
}
```

where `ifexp` may be

<table>
<thead>
<tr>
<th><code>ifexp</code></th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>(ifexp)</code></td>
<td>order of evaluation</td>
</tr>
<tr>
<td><code>!ifexp</code></td>
<td>logical not</td>
</tr>
<tr>
<td>`ifexp</td>
<td>ifexp`</td>
</tr>
<tr>
<td><code>ifexp &amp; ifexp</code></td>
<td>logical and</td>
</tr>
<tr>
<td><code>vname</code></td>
<td>true if <code>vname</code> is not 0 and not &quot;&quot;</td>
</tr>
<tr>
<td><code>vname.booleanfunction</code></td>
<td>true if <code>vname.booleanfunction</code> evaluates to true</td>
</tr>
<tr>
<td><code>_rc</code></td>
<td>see 5.5 Command-execution commands</td>
</tr>
<tr>
<td><code>_stbusy</code></td>
<td>true if Stata is busy</td>
</tr>
<tr>
<td><code>H(vname)</code></td>
<td>true if <code>vname</code> is hidden or disabled</td>
</tr>
<tr>
<td><code>default(vname)</code></td>
<td>true if <code>vname</code> is its default value</td>
</tr>
</tbody>
</table>

Note the recursive definition: An `ifexp` may be substituted into itself to produce more complicated expressions, such as `((!d1.s1) & d1.s2) | d1.s3.isdefault()`. 

Also note that the order of evaluation is left to right; use parentheses.

<table>
<thead>
<tr>
<th>booleanfunction</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>isdefault()</td>
<td>true if the value of vname is its default value</td>
</tr>
<tr>
<td>isenabled()</td>
<td>true if vname is enabled</td>
</tr>
<tr>
<td>isnumlist()</td>
<td>true if the value of vname is a numlist</td>
</tr>
<tr>
<td>isvisible()</td>
<td>true if vname is visible</td>
</tr>
<tr>
<td>isvalidname()</td>
<td>true if the value of vname is a valid Stata name</td>
</tr>
<tr>
<td>isvarname()</td>
<td>true if the value of vname is the name of a variable in the current dataset</td>
</tr>
<tr>
<td>iseq(argument)</td>
<td>true if the value of vname is equal to argument</td>
</tr>
<tr>
<td>isneq(argument)</td>
<td>true if the value of vname is not equal to argument</td>
</tr>
<tr>
<td>isgt(argument)</td>
<td>true if the value of vname is greater than argument</td>
</tr>
<tr>
<td>isge(argument)</td>
<td>true if the value of vname is greater than or equal to argument</td>
</tr>
<tr>
<td>islt(argument)</td>
<td>true if the value of vname is less than argument</td>
</tr>
<tr>
<td>isle(argument)</td>
<td>true if the value of vname is less than or equal to argument</td>
</tr>
<tr>
<td>isNumlistEQ(argument)</td>
<td>true if every value of vname is equal to argument, where vname may be a numlist</td>
</tr>
<tr>
<td>isNumlistLT(argument)</td>
<td>true if every value of vname is less than argument, where vname may be a numlist</td>
</tr>
<tr>
<td>isNumlistLE(argument)</td>
<td>true if every value of vname is less than or equal to argument, where vname may be a numlist</td>
</tr>
<tr>
<td>isNumlistGT(argument)</td>
<td>true if every value of vname is greater than argument, where vname may be a numlist</td>
</tr>
<tr>
<td>isNumlistGE(argument)</td>
<td>true if every value of vname is greater than or equal to argument, where vname may be a numlist</td>
</tr>
<tr>
<td>isNumlistInRange(arg1,arg2)</td>
<td>true if every value of vname is in between arg1 and arg2 inclusive, where vname may be a numlist</td>
</tr>
<tr>
<td>startswith(argument)</td>
<td>true if the value of vname starts with argument</td>
</tr>
<tr>
<td>endswith(argument)</td>
<td>true if the value of vname ends with argument</td>
</tr>
<tr>
<td>contains(argument)</td>
<td>true if the value of vname contains argument</td>
</tr>
<tr>
<td>iseqignorecase(argument)</td>
<td>true if the value of vname is equal to argument ignoring case</td>
</tr>
</tbody>
</table>

An argument can be a dialog control, a dialog property, or a literal. If the argument is a literal it can be either string or numeric, depending on the type of control the booleanfunction references. String controls require that literals be quoted, and numeric controls require that literals not be quoted.

Description

if executes the code inside the braces if ifexp evaluates to true and skips it otherwise. When an else has been specified, the code within its braces will be executed if ifexp evaluates to false. if commands may be nested.

Example

```plaintext
if d1.v1.isvisible() {
    put "thing=" d1.v1
}
else {
    put "thing=" d1.v2
}
```
5.2.2 while

Syntax

```dialog
while condition {
  ...
}
```

where `condition` may be

<table>
<thead>
<tr>
<th>condition</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(condition)</td>
<td>order of evaluation</td>
</tr>
<tr>
<td>!condition</td>
<td>logical not</td>
</tr>
<tr>
<td>condition</td>
<td>condition</td>
</tr>
<tr>
<td>condition &amp; condition</td>
<td>logical and</td>
</tr>
</tbody>
</table>

Description

A `while` loop is for circumstances where you want to do the same thing repeatedly. It is controlled by a counter. For a `while` loop to execute correctly, you must do the following:

1. Initialize a start value for the counter before the loop.
2. Specify a condition that tests the value of the counter against its expected final value such that the logical condition evaluates to false and the loop is forced to end at some point.
3. Specify a command that modifies the value of the counter inside the loop.

Example

```dialog
PROGRAM testprog
  call create DOUBLE i
  call create ARRAY testlist
  while(i.islt(10)) {
    call i.withvalue testlist.Arrpush @
    call i.increment
  }
END
```
5.2.3 call

Syntax

```dialog
call iaction
```

where `iaction` is

- `action memberfunction`
- `gaction dialogname.controlname.memberfunction`
- `dialogname.controlname.memberfunction`
- `script scriptname`
- `view topic`
- `program programname`

`iaction “action memberfunctionname”` is invalid in u-action programs because there is no concept of a current control.

Description

`call` executes the specified `iaction`. If an `iaction` is not specified, `gaction` is assumed.

Example

```dialog
PROGRAM testprog
BEGIN
  if sample.cb1 & sample.cb2 {
    call gaction sample.txt1.disable
  }
  if !(sample.cb1 & sample.cb2) {
    call gaction sample.txt1.enable
  }
END
```

5.2.4 exit

Syntax

```dialog
exit [\#]
```

where `\# \geq 0`. The following exit codes have special meaning:

<table>
<thead>
<tr>
<th>#</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>exit without error</td>
</tr>
<tr>
<td>&gt;0</td>
<td>exit with error</td>
</tr>
<tr>
<td>101</td>
<td>program exited because of a missing required object</td>
</tr>
</tbody>
</table>
Dialog programming — Dialog programming

Description

exit causes the program to exit and, optionally, to return #.

exit without an argument is equivalent to “exit 0”. In u-action programs, the cmdstring, optstring will be sent to Stata for execution.

exit #, # > 0, indicates an error. In u-action programs, the cmdstring, optstring will not be executed. exit 101 has special meaning. When a u-action program exits, Stata checks the exit code for that program and, if it is 101, presents an error box stating that the user forgot to fill in a required element of the dialog box.

Example

if !sample.var1 {
    exit 101
}

5.2.5 close

Syntax

close

Description

close causes the dialog box to close.

5.3 Error-checking and presentation commands

5.3.1 require

Syntax

require ename [ename [ . . .]]

where each ename must be string.

Description

require does nothing on each ename that is disabled or hidden.

For other enames, require requires that the controls specified not be empty ("") and produces a stop-box error message such as “dependent variable must be defined” for any that are empty. The “dependent variable” part of the message will be obtained from the control’s error() option or, if that was not specified, from the control’s label() option; if that was not specified, a generic error message will be displayed.

Example

require main.grpvar
5.3.2 stopbox

Syntax

```
stopbox { stop | note | rusure } [ "line1" [ "line2" [ "line3" [ "line4" ] ] ] ]
```

Description

stopbox displays a message box containing up to four lines of text. Three types are available:
- **stop**: Displays a message box in which there is only one button, OK, which means that the user must accept that he or she made an error and correct it. The program will exit after stopbox stop.
- **note**: Displays a message box in which there is only one button, OK, which confirms that the user has read the message. The program will continue after stopbox note.
- **rusure**: Displays a message box in which there are two buttons, Yes and No. The program will continue if the user clicks on Yes or exit if the user clicks on No.

Also see [P] window stopbox for more information.

Example

```
stopbox stop "Nothing has been selected"
```

5.4 Command-construction commands

The command-construction commands are

- **by**
- **bysort**
- **put**
- **varlist**
- **ifexp**
- **inrange**
- **weight**
- **beginoptions/option/optionarg/endoptions**
- **allowxi/\(x\)i**
- **clear**

Most correspond to the part of Stata syntax for which they are named:

- **by varlist**: cmd varlist [ if ] [ in ] [ weight ] [ , options ]

**put** corresponds to cmd (although it is useful for other things as well), and **allowxi/\(x\)i** corresponds to putting \(x\)i: in front of the entire command; see [R] \(x\)i.

The command-construction commands (with the exception of \(x\)i) build cmdstring and optstring in the order the commands are executed (see 5.1.3 rstrings: cmdstring and optstring), so you should issue them in the same order they are used in Stata syntax.
Added to the syntax diagrams that follow is a new header:

Use of option() communication.

This refers to the option() option on the input control definition, such as CHECKBOX and EDIT; see 2.6 U-actions and communication options.

5.4.1 by

Syntax

\texttt{by \ ename}

where \texttt{ename} must contain a string and should refer to a VARNAME, VARLIST, or EDIT control.

Use of option() communication: None.

Description

by adds nothing to the current rstring if \texttt{ename} is hidden, disabled, or empty. Otherwise, by outputs “by \texttt{varlist}:”, followed by a blank, obtaining a varlist from \texttt{ename}.

Example

\texttt{by d2.by}

5.4.2 bysort

Syntax

\texttt{bysort \ ename}

where \texttt{ename} must contain a string and should probably refer to a VARNAME, VARLIST, or EDIT control.

Use of option() communication: None.

Description

bysort adds nothing to the current rstring if \texttt{ename} is hidden, disabled, or empty. Otherwise, bysort outputs “by \texttt{varlist}, \texttt{sort} :”, followed by a blank, obtaining a varlist from \texttt{ename}.

Example

\texttt{bysort d2.by}
5.4.3 put

Syntax

\[
\text{put } [\%fmt] \text{ putel } [\%fmt] \text{ putel } [...] \]

where putel may be

""
"string"
\vname
\hidden \vname
\on \vname
\program \programname

The word “output” means “add to the current result” in what follows. The put directives are defined as

"" and "string"
Outputs the fixed text specified.
\vname
Outputs the value of the control.
\hidden \vname
Outputs the value of the control, even if it is hidden or disabled.
\on \vname
Outputs nothing if \vname==0. \vname must be numeric and should be the result of a CHECKBOX or RADIO control. \on outputs the text from the control’s \text{option()} option. Also see 5.4.8.1 \text{option} for an alternative using the \text{option} command.
\program \programname
Outputs the \cmdstring, \optstring returned by \programname.

If any \vname is disabled or hidden and not preceded by \hidden, put outputs nothing.
If the directive is preceded by \%fmt, the specified \%fmt is always used to format the result. Otherwise, string results are displayed as is, and numeric results are displayed in \%10.0g format and stripped of resulting leading and trailing blanks. See [D] \text{format}.

Use of \text{option()} communication: See /on above.

Description

\text{put} adds to the current \rstring (outputs) what is specified.

Remarks

\text{put "string"} is often used to add the Stata command to the current \rstring. When used in that way, the right way to code is

\text{put "commandname "}

Note the trailing blank on \text{commandname}; see 5.1.4 Adding to an \rstring.

\text{put} displays nothing if any element specified is hidden or disabled. For instance,

\text{put "thing=" d1.v1}
will output nothing (not even \texttt{"thing="}) if \texttt{d1.v1} is hidden or disabled. This saves you from having to code

\begin{verbatim}
    if !h(d1.v1) {
        put "thing=" d1.v1
    }
\end{verbatim}

\section*{5.4.4 \texttt{varlist}}

\textbf{Syntax}

\begin{verbatim}
    \texttt{varlist el [el [...]]}
\end{verbatim}

where an \textit{el} is \textit{ename} or \texttt{[ename]} (brackets significant).

Each \textit{ename} must be string and should be the result from a \texttt{VARLIST}, \texttt{VARNAME}, or \texttt{EDIT} control. If \textit{ename} is not enclosed in brackets, it must not be hidden or disabled.

Use of \texttt{option()} communication: None.

\textbf{Description}

\texttt{varlist} considers it an error if any of the specified \textit{enames} that are not enclosed in brackets are hidden or disabled or empty (contain \texttt{""}).

In these cases, \texttt{varlist} displays a stop-message box indicating that the varlist must be filled in and exits the program.

\texttt{varlist} adds nothing to the current rstring if any of the specified \textit{enames} that are enclosed in brackets are hidden or disabled.

Otherwise, \texttt{varlist} outputs with leading and trailing blanks the contents of each \textit{ename} that is not hidden, is not disabled, and does not contain \texttt{""}.

\textbf{Remarks}

\texttt{varlist} is most often used to output the varlist of a Stata command, such as

\begin{verbatim}
    varlist main.depvar [main.indepvars]
\end{verbatim}

\texttt{varlist} can also be used for other purposes. You might code

\begin{verbatim}
    if d1.v1 {
        put " exog("
        varlist d2.v1
        put ") "
    }
\end{verbatim}

although coding

\begin{verbatim}
    optionarg d2.v1
\end{verbatim}

would be an easier way to achieve the same effect.
5.4.5 ifexp

Syntax

\[ \text{ifexp } \text{ename} \]

where \text{ename} must be a string control.

Use of \text{option()} communication: None.

Description

ifexp adds nothing to the current rstring if \text{ename} is hidden, disabled, or empty. Otherwise, output is “if exp”, with spaces added before and after.

Example

\[ \text{if } d2.\text{if} \]

5.4.6 inrange

Syntax

\[ \text{inrange } \text{ename}_1 \text{ ename}_2 \]

where \text{ename}_1 and \text{ename}_2 must be numeric controls.

Use of \text{option()} communication: None.

Description

If \text{ename}_1 is hidden or disabled, results are as if \text{ename}_1 were not hidden and contained 1. If \text{ename}_2 is hidden or disabled, results are as if \text{ename}_1 were not hidden and contained \_N, the number of observations in the dataset.

If \text{ename}_1==1 \text{ and ename}_2==\_N, nothing is output (added to the current rstring).

Otherwise, “in range” is output with spaces added before and after, with the range obtained from \text{ename}_1 and \text{ename}_2.

Example

\[ \text{inrange } d2.\text{in1} \text{ d2.in2} \]

5.4.7 weight

Syntax

\[ \text{weight } \text{ename}_t \text{ ename}_e \]

where \text{ename}_t may be a string or numeric control and must have had \text{option()} filled in with a weight type (one of \text{weight}, \text{fweight}, \text{aweight}, \text{pweight}, or \text{iweight}), and \text{ename}_e must be a string evaluating to the weight expression or variable name.

Use of \text{option()} communication: \text{ename}_t must have \text{option()} filled in the weight type.
Description

weight adds nothing to the current rstring if ename\_t or ename\_e are hidden, disabled, or empty. Otherwise, output is [weighttype=exp] with leading and trailing blanks.

Remarks

weight is typically used as

weight radio(d1 w1 w2 . . . wk) d1.wexp

where d1.w1, d1.w2, . . ., d1.wk are radio buttons, which could be defined as

```
DIALOG d1 . . .
BEGIN
  . . .
  RADIO w1 . . . , . . . label(fweight) first . . .
  RADIO w2 . . . , . . . label(aweight) . . .
  RADIO w3 . . . , . . . label(pweight) . . .
  RADIO w4 . . . , . . . label(iweight) last . . .
  . . .
END
```

Not all weight types need to be offered. If a command offers only one kind of weight, you do not need to use radio buttons. You could code

```
weight d1.wt d1.wexp
```

where d1.wt was defined as

```
CHECKBOX wt . . . , . . . label(fweight) . . .
```

5.4.8 beginoptions and endoptions

Syntax

```
beginoptions
  any dialog-programming command except beginoptions
  . . .
endoptions
```

Use of option() communication: None.

Description

beginoptions/endoptions indicates that you wish what is enclosed to be treated as Stata options in constructing cmdstring, optstring.

The current rstring is, by default, cmdstring. beginoptions changes the current rstring to optstring. endoptions changes it back to cmdstring. So there are two strings being built. When the dialog program exits normally, if there is anything in optstring, trailing spaces are removed from cmdstring, a comma and a space are added, the contents of optstring are added, and all that is returned. Thus a dialog program can have many beginoptions/endoptions blocks, but all the options will appear at the end of the cmdstring.

The command-construction commands option and optionarg are documented below because they usually appear inside a beginoptions/endoptions block, but they can be used outside beginoptions/endoptions blocks, too. Also all the other command-construction commands can be used inside a beginoptions/endoptions block, and using put is particularly common.
5.4.8.1 option

Syntax

    option ename [ename [ . . .]]

where ename must be a numeric control with 0 indicating that the option is not desired.

Use of option() communication: option() specifies the name of the option.

Description

    option adds nothing to the current rstring if any of the enames specified are hidden or disabled. Otherwise, for each ename specified, if ename is not equal to 0, the contents of its option() are displayed.

Remarks

    option is an easy way to output switch options such as noconstant and detail. You simply code

        option d1.sw

where you have previously defined

    CHECKBOX sw . . . , option(detail) . . .

    Here detail will be output if the user checked the box.

5.4.8.2 optionarg

Syntax

    optionarg [style] ename [[style] ename [ . . .]]

where each ename may be a numeric or string control and style is

<table>
<thead>
<tr>
<th>style</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>/asis</td>
<td>do not quote</td>
</tr>
<tr>
<td>/quoted</td>
<td>do quote</td>
</tr>
<tr>
<td>/oquoted</td>
<td>quote if necessary</td>
</tr>
<tr>
<td>%fmt</td>
<td>for use with numeric</td>
</tr>
</tbody>
</table>

Use of option() communication: option() specifies the name of the option.

Description

    optionarg adds nothing to the current rstring if any of the enames specified are hidden or disabled. Otherwise, for each ename specified, if ename is not equal to "", the ename’s option() is output, followed by “(”, the ename’s contents, and “)” with blanks added before and after.
Remarks

optionarg is an easy way to output single-argument options such as title() or level(); for example,

    optionarg /quoted d1.ttl
    if ! d1.level.isdefault() {
        optionarg d1.level
    }

where you have previously defined

    EDIT    ttl . . . , . . . label(title) . . .
    SPINNER level . . . , . . . label(level) . . .

5.5 Command-execution commands

Commands are executed automatically when a program is invoked by an input control’s uaction() option. Programs so invoked are called u-action programs. No command is executed when a program is invoked by an input control’s iaction() option. Programs so invoked are called i-action programs.

The stata and clear commands are for use if

1. you want to write a u-action program that executes more than one Stata command, or
2. you want to write an i-action program that executes one or more Stata commands (also known as heavyweight i-action programs).

5.5.1 stata

Syntax

    stata

    stata hidden [immediate|queue]

Use of option() communication: None.

Description

    stata executes the current cmdstring, optstring and displays the command in the Results window before execution, just as if the user had typed it.

    stata hidden executes the current cmdstring, optstring but does not display the command in the Results window before execution. stata hidden may optionally be called with either of two modifiers: queue or immediate. If neither modifier is specified, immediate is implied.

    immediate causes the command to execute at once, waits for the command to finish, and sets _rc to contain the return code. Because the command is to be executed immediately, the dialog engine will complain if Stata is not idle.

    queue causes the command to be placed into the command buffer, allowing it to be executed as soon as Stata becomes idle. The behavior of stata and stata hidden queue are identical except that stata hidden queue does not echo the command.
**Important notes about stata hidden immediate**

A unique situation can occur when `stata hidden immediate` is used in an **initialization script or program**. Stata dialogs are considered asynchronous, meaning that Stata dialogs can be loaded through the menu and help systems even when Stata is busy processing an ado program. Because `stata hidden immediate` relies on ado processing and because ado processing is synchronous, dialogs that call `stata hidden immediate` during initialization can only be used synchronously. That means these types of dialogs cannot be loaded while Stata is busy processing other tasks. Because of this, the dialog must be notified that it is special in this regard. This is done by placing the dialog directive `SYNCHRONOUS_ONLY` in the dialog box program just after the `VERSION` statement.

`SYNCHRONOUS_ONLY` performs one other important function. Dialogs that are launched by using the `db` command cause Stata to become busy and remain busy until the dialog is completely loaded. After all, `db` is an ado program, and until the dialog loads and `db` subsequently exits execution, Stata is busy. The `SYNCHRONOUS_ONLY` directive lets the dialog engine know that executing `stata hidden immediate` during initialization routines is allowed even when the dialog is launched with an ado program.

### 5.5.2 clear

**Syntax**

```
clear [ curstring|cmdstring|optstring ]
```

Use of `option()` communication: None.

**Description**

`clear` is seldom used and is typically specified without arguments. `clear` clears (resets to "") the specified return string or, if it is specified without arguments, clears `cmdstring` and `optstring`. If `curstring` is specified, `clear` clears the current return string, which is `cmdstring` by default or `optstring` within a `beginoptions/endoptions` block.

### 5.6 Special scripts and programs

Sometimes, it may be useful to have a script or program run automatically, either just before dialog-box controls are created or just after. The following scripts and programs are special, and when they are defined, they run automatically.

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREINIT_SCRIPT</td>
<td>script that runs before any dialog box controls are created</td>
</tr>
<tr>
<td>PREINIT_PROGRAM</td>
<td>program that runs before any dialog box controls are created</td>
</tr>
<tr>
<td>POSTINIT_SCRIPT</td>
<td>script that runs after all dialog box controls are created</td>
</tr>
<tr>
<td>POSTINIT_PROGRAM</td>
<td>program that runs after all dialog box controls are created</td>
</tr>
<tr>
<td>PREINIT</td>
<td>shortcut for PREINIT_SCRIPT</td>
</tr>
<tr>
<td>POSTINIT</td>
<td>shortcut for POSTINIT_SCRIPT</td>
</tr>
<tr>
<td>ON_DOTPROMPT</td>
<td>program that runs when Stata returns from executing an interactive command; <code>ON_DOTPROMPT</code> program should never call the dialog system’s <code>stata</code> command, because that would result in infinite recursion</td>
</tr>
</tbody>
</table>
Often it is desirable to encapsulate individual dialog tabs into .idlg files, particularly when a dialog tab is used in many different dialog boxes. In those circumstances, a dialog tab can use its own initialization script or program. The following naming conventions are used to define these scripts and programs.

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>tabname_PREINIT_SCRIPT</td>
<td>script that runs before controls on dialog tabname are created</td>
</tr>
<tr>
<td>tabname_PREINIT_PROGRAM</td>
<td>program that runs before controls on dialog tabname are created</td>
</tr>
<tr>
<td>tabname_POSTINIT_SCRIPT</td>
<td>script that runs after controls on dialog tabname are created</td>
</tr>
<tr>
<td>tabname_POSTINIT_PROGRAM</td>
<td>program that runs after controls on dialog tabname are created</td>
</tr>
<tr>
<td>tabname_PREINIT</td>
<td>shortcut for tabname_PREINIT_SCRIPT</td>
</tr>
<tr>
<td>tabname_POSTINIT</td>
<td>shortcut for tabname_POSTINIT_SCRIPT</td>
</tr>
</tbody>
</table>

The order of execution for dialog initialization is as follows:

1. Execute PREINIT script or program for the dialog box.
2. Execute PREINIT scripts and programs for each dialog tab using the order in which the tabs are created.
3. Create all controls for the entire dialog box.
4. Execute POSTINIT scripts and programs for each dialog tab using the order in which the tabs are created.
5. Execute POSTINIT script or program for the dialog box.

6. Properties

Properties are used to store information that is useful for dialog box programming. Properties may be of type STRING, DOUBLE, or BOOLEAN and do not have a visual representation on the dialog box. Special variants of these basic types are available. These variants, PSTRING, PDOUBLE, and PBOOLEAN, are considered persistent and are identical to their counterparts. The contents of these persistent types do not get destroyed when a dialog is reset. Usually, the base types should be used. Application of the persistent types should be reserved for special circumstances. See create for information about creating new instances of a property.

Member functions

**STRING**

propertyname.setvalue strvalue
propertyname.setstring strvalue; synonym for .setvalue
propertyname.append strvalue

</tbody>
</table>
```

7. Child dialogs

**Syntax**
```
create CHILD dialogname [AS referenceName] [ , nomodal allowsubmit allowcopy message(string) ]
```
Member functions

`settitle string` sets the title text of the child dialog box

`setExitString string` informs the child where to save the command string when the OK or Submit button is clicked on

`setOkAction string` informs the child that it is to invoke a specific action in the parent when the OK button is clicked on and the child exits

`setSubmitAction string` informs the child that it is to invoke a specific action in the parent when the Submit button is clicked on

`setExitAction string` informs the child that it is to invoke a specific action in the parent when the OK or Submit button is clicked on; note that `setExitAction` has the same effect as calling both `setOkAction` and `setSubmitAction` with the same argument

`create property` allows the parent to create properties in the child; see 6. Properties

`callthru gaction` allows the parent to call global actions in the context of the child

Description

Child dialogs are dialogs that are spawned by another dialog. These dialogs form a relationship where the initial dialog is referred to as the parent and all dialogs spawned from that parent are referred to as its children. In most circumstances, the children collect information and return that information to the parent for later use. Unless `AS reference name` has been specified, children are referenced through the `dialogname`.

Options

`nomodal` suppresses the default modal behavior of a child dialog unless the `MODAL` directive was specifically used inside the child dialog resource file.

`allowsubmit` allows for the use of the Submit button on the dialog box. By default, the Submit button is removed if it has been declared in the child dialog resource file.

`allowcopy` allows for the use of the Copy button on the dialog box. By default, the Copy button is removed if it has been declared in the child dialog resource file.

`message(string)` specifies that `string` be passed to the child dialog box, where it can be referenced from STRING property named `__MESSAGE`.

7.1 Referencing the parent

While it is normally not necessary, it is sometimes useful for a child dialog box to give special instructions or information to its parent. All child dialog boxes contain a special object named PARENT, which can be used with a member program named `callthru`. PARENT.callthru can be used to call any intermediate action in the context of the parent dialog box.
8. Example

The following example will execute the `summarize` command. In addition to the copy below, a copy can be found among the Stata distribution materials. You can type

```
. which sumexample.dlg
```

to find out where it is.

```
// sumexample
// version 1.0.0
VERSION 15.0
POSITION . . 320 200
DIALOG main, title("Example simple summarize dialog") tabtitle("Main")

sumexample.dlg

Appendix A: Jargon

**action:** See *i-action* and *u-action*.

**browser:** See *file chooser*.

**button:** A type of input control; a button causes an i-action to occur when it is clicked on. Also see *u-action buttons*, *helper buttons*, and *radio buttons*.

**checkbox:** A type of numeric input control; the user may either check or uncheck what is presented; suitable for obtaining yes/no responses. A checkbox has value 0 or 1, depending on whether the item is checked.

**combo box:** A type of string input control that has an edit field at the top and a list box underneath. Combo boxes come in three flavors:

A regular combo box has an edit field and a list below it. The user may choose from the list or type into the edit field.

A drop-down combo box also has an edit field and a list, but only the edit field shows. The user can click to expose the list. The user may choose from the list or type in the edit field.

A drop-down-list combo box is more like a list box. An edit field is displayed. The list is hidden, and the user can click to expose the list, but the user can only choose elements from the list; he or she cannot type in the edit field.

**control:** See *input control* and *static control*.

**control status:** Whether a control (input or static) is disabled or enabled, hidden or shown.

**dialog(s):** The main components of a dialog box in that the dialogs contain all the controls except for the u-action buttons.

**dialog box:** Something that pops up onto the screen that the user fills in; when the user clicks on an action button, the dialog box causes something to happen (namely, Stata to execute a command).

A dialog box is made up of one or more dialogs, u-action buttons, and a title bar.
If the dialog box contains more than one dialog, only one of the dialogs shows at a time, which one being determined by the tab selected.

dialog program: See PROGRAM.

disabled and enabled: A control that is disabled is visually grayed out; otherwise, it is enabled. The user cannot modify disabled input controls. Also see hidden and exposed.

dlg file: The file containing the code defining a dialog box and its actions. If the file is named \textit{xyz}\_dlg, the dialog box is said to be named \textit{xyz}.

dlg-program: The entire contents of a .dlg file; the code defining a dialog box and its actions.

edit field: A type of string input control; a box in which the user may type text.

enabled and disabled: See hidden and exposed.

exposed and hidden: See hidden and exposed.

file browser: See file chooser.

file chooser: A type of string input control; presents a list of files from which the user may choose one or type a filename.

frame: A type of static control; a rectangle drawn around a group of controls.

group box: A type of static control; a rectangle drawn around a group of controls with descriptive text at the top.

helper buttons: The buttons Help and Reset. When Help is clicked on, the help topic for the dialog box is displayed. When Reset is clicked on, the control values of the dialog box are reset to their defaults.

hidden and exposed: A control that is removed from the screen is said to be hidden; otherwise, it is exposed. Hidden input controls cannot be manipulated by the user. A control would also not be shown when it is contained in a dialog that does not have its tab selected in a multidialog dialog box; in this case, it may be invisible, but whether it is hidden or exposed is another matter. Also see hidden and exposed.

i-action: An intermediate action usually caused by the interaction of a user with an input control, such as hiding or showing and disabling or enabling other controls; opening the Viewer to display something; or executing a SCRIPT or a PROGRAM.

input control: A screen element that the user fills in or sets. Controls include checkboxes, buttons, radio buttons, edit fields, spinners, file choosers, etc. Input controls have (set) values, which can be string, numeric, or special. These values reflect how the user has “filled in” the control. Input controls are said to be string or numeric depending on the type of result they obtain (and how they store it).

Also see static control.

label or title: See title or label.

list: A programming concept; a vector of elements.

list box: A type of string input control; presents a list of items from which the user may choose. A list box has (sets) a string value.

numeric input control: An input control that returns a numeric value associated with it.

position: Where something is located, measured from the top left by how far to the right it is (x) and how far down it is (y).
**PROGRAM:** A programming concept dealing with the implementation of dialogs. Programs may be used to implement i-actions or u-actions. Also see **SCRIPT**.

**radio buttons:** A set of numeric input controls, each a button, of which only one may be selected at a time; suitable for obtaining categorical responses. Each radio button in the set has (sets) a numeric value, 0 or 1, depending on which button is selected. Only one in the set will be 1.

**SCRIPT:** A programming concept dealing with the implementation of dialogs. An array of i-actions to be executed one after the other; errors that occur do not stop subsequent actions from being attempted. Also see *PROGRAM*.

**size:** How large something is, measured from its top-left corner, as a width \( x_{\text{size}} \) and height \( y_{\text{size}} \). Height is measured from the top down.

**spinner:** A type of numeric input control; presents a numeric value that the user may increase or decrease over a range. A spinner has (sets) a numeric value.

**static control:** A screen element similar to an input control, except that the end user cannot interact with it. Static controls include static text and lines drawn around controls visually to group them together (group boxes and frames). Also see control and input control.

**static text:** A static control specifying text to be placed on a dialog.

**string input control:** An input control that returns a string value associated with it.

**tabs:** The small labels at the top of each dialog (when there is more than one dialog associated with the dialog box) and on which the user clicks to select the dialog to be filled in.

**title or label:** The fixed text that appears above or on objects such as dialog boxes and buttons. Controls are usually said to be labeled, whereas dialog boxes are said to be titled.

**u-action:** What a dialog box causes to happen after the user has filled it in and clicked on a u-action (ultimate action) button. The point of a dialog box is to result in a u-action.

**u-action buttons:** The buttons OK, Submit, Cancel, and Copy; clicking on one causes the ultimate action (u-action) associated with the button to occur and, perhaps, the dialog box to close.

**varlist or varname control:** A type of string input control; an edit field that also accepts input from the Variables window. This control also contains a combo-box-style list of the variables. A varlist or varname control has (sets) a string value.

**Appendix B: Class definition of dialog boxes**

Dialog boxes are implemented in terms of class programming; see [P] class.

The top-level class instance of a dialog box defined in `dialogbox.d1g` is `.dialogbox_d1g`. Dialogs and controls are nested within that, so `.dialogbox_d1g.dialogname` would refer to a dialog, and `.dialogbox_d1g.dialogname.controlname` would refer to a control in the dialog.

`.dialogbox_d1g.dialogname.controlname.value` is the current value of the control, which will be either a string or a double. You must not change this value.

The member functions of the controls are implemented as member functions of `.dialogbox_d1g.dialogname.controlname` and may be called in the standard way.
Appendix C: Interface guidelines for dialog boxes

One of Stata’s strengths is its strong support for cross-platform use—datasets and programs are completely compatible across platforms. This includes dialogs written in the dialog-programming language. Although Mac, Windows, and X Windows share many common graphical user-interface elements and concepts, they all vary slightly in their appearance and implementation. This variation makes it difficult to design dialogs that look and behave the same across all platforms. Dialogs should look pleasant on screen to enhance their usability, and achieving this goal often means being platform specific when laying out controls. This often leads to undesirable results on other platforms.

The dialog-programming language was written with this in mind, and dialogs that appear and behave the same across multiple operating systems and appear pleasant can be created by following some simple guidelines.

**Use default heights where applicable:** Varying vertical-size requirements of controls across different operating systems can cause a dialog that appears properly on one platform to display controls that overlap one another on another platform. Using the default *ysize* of . takes these variations into account and allows for much easier placement and alignment of controls. Some controls (list boxes, regular combo boxes, group boxes, and frames) still require their *ysize* to be specified because their vertical size determines how much information they can reveal.

**Use all horizontal space available:** Different platforms use different types of fonts to display text labels and control values. These variations can cause some control labels to be truncated (or even word wrapped) if their *xsize* is not large enough for a platform’s system font. To prevent this from happening, specify an *xsize* that is as large as possible. For each column of controls, specify the entire column width for each control’s *xsize*, even for controls where it is obviously unnecessary. This reduces the chances of a control’s label being truncated on another platform and also allows you to make changes to the label without constantly having to adjust the *xsize*. If your control barely fits into the space allocated to it, consider making your dialog slightly larger.

**Use the appropriate alignment for static text controls:** The variations in system fonts also make it difficult to horizontally align static text controls with other controls. Placing a static text control next to an edit field may look good on one platform but show up with too much space between the controls on another or even show up truncated.

One solution is to place static text controls above controls that have an edit field and make the static text control as wide as possible. This gives more room for the static text control and makes it easier to left-justify it with other controls.

When placing a static text control to the left of a control is more appropriate (such as From: and To: edit fields), use right-alignment rather than the default left-alignment. The two controls will then be equally spaced apart on all platforms. Again be sure to make the static text control slightly wider than necessary—do not try to left-justify a right-aligned static text control with controls above and below it because it may not appear left-justified on other platforms or may even be truncated.

**Do not crowd controls:** Without making your dialog box unnecessarily large, use all the space that is available. Organize related controls close together, and put some distance between unrelated ones. Do not overload users with lots of controls in one dialog. If necessary, group controls in separate dialogs. Most importantly, be consistent in how you layout controls.

**All vertical size and spacing of controls involves multiples of 10 pixels:** The default *ysize* for most controls is 20 pixels. Related controls are typically spaced 10 pixels apart, and unrelated ones are at least 20 pixels apart.

**Use the appropriate control for the job:** Checkboxes have two states: on or off. A radio-button group consisting of two radio buttons similarly has two states. A checkbox is appropriate when the
action taken is either on or off or easy to infer (for example, Use constant). A two-radio-button group is appropriate when the opposite state cannot be inferred (for example, Display graph and Display table).

Radio-button groups should contain at least two radio buttons and no more than about seven. If you need more choices, consider using a drop-down-list combo box or, if the number of choices is greater than about 12, a list box. If you require a control that allows multiple selections, consider a regular combo box or drop-down combo box. Drop-down combo boxes can be cumbersome to use if the number of choices is great, so use a regular combo box unless space is limited.

**Understand control precedence for mouse clicks:** Because of the limited size of dialogs, you may want to place several controls within the same area and hide and show them as necessary. It is also useful to place controls within other controls, such as group boxes and frames, for organizational and presentational purposes. However, the order of creation and placement and size of controls can affect which controls receive mouse clicks first or whether they receive them at all.

The control where this can be problematic is the radio button. On some platforms, the space occupied by a group of radio buttons is not the space occupied by the individual radio buttons. It is inclusive to the space occupied by the radio button that is closest to the top-left corner of the dialog, the widest radio button, and the bottommost radio button. To prevent a group of radio buttons from preventing mouse clicks being received by other controls, Stata gives precedence to all other controls except for group boxes and frames. The order of precedence for controls that can receive mouse clicks is the following: first, all controls other than radio buttons and checkbox group boxes, then radio buttons, then checkbox group boxes.

If you intend to place two or more groups of radio buttons in the same area and show and hide them as necessary, be sure that when you hide the radio buttons from a group, you hide all radio buttons from a group. The radio-button group with precedence over other groups will continue to have precedence as long as any of its radio buttons are visible. Mouse clicks in the space occupied by nonvisible radio buttons in a group with precedence will not pass through to any other groups occupying the same space.

It is always safe to place controls within frames, group boxes, and checkbox group boxes because all other controls take precedence over those controls.

In practice, you should never hide a radio button from a group without hiding the rest of the radio buttons from the group. Consider simply disabling the radio button or buttons instead. It is also not a good idea to hide or show radio buttons from different groups to make them appear that they are from the same group. That simply will not work on some platforms and is generally a bad idea, anyway.

Radio buttons have precedence over checkbox group boxes. You may place radio buttons within a checkbox group box, but do not place a checkbox group box within the space occupied by a group of radio buttons. If you do, you may not be able to click on the checkbox control on some platforms.

**Frequently asked questions**

See [dialog programming FAQs](https://www.stata.com/support/faqs/) on the Stata website.

**Also see**

[P] window programming — Programming menus and windows

[R] db — Launch dialog
**Description**

discard drops all automatically loaded programs (see [U] 17.2 What is an ado-file?); clears e(), r(), and s() stored results (see [P] return); eliminates information stored by the most recent estimation command and any other saved estimation results (see [P] ereturn); closes any open graphs and drops all sersets (see [P] serset); clears all class definitions and instances (see [P] classutil); clears all business calendars (see [D] datetime business calendars); and closes all dialogs and clears their remembered contents (see [P] dialog programming).

In short, discard causes Stata to forget everything current without forgetting anything important, such as the data in memory.

**Syntax**

discard

**Remarks and examples**

Use discard to debug ado-files. Making a change to an ado-file will not cause Stata to update its internal copy of the changed program. discard clears all automatically loaded programs from memory, forcing Stata to refresh its internal copies with the versions residing on disk.

Also all of Stata’s estimation commands can display their previous output when the command is typed without arguments. They achieve this by storing information on the problem in memory. predict (see [R] predict) calculates various statistics (predictions, residuals, influence statistics, etc.), estat vce (see [R] estat vce) shows the covariance matrix, lincom (see [R] lincom) calculates linear combinations of estimated coefficients, and test and testnl (see [R] test and [R] testnl) perform hypotheses tests, all using that stored information. discard eliminates that information, making it appear as if you never fit the model.

Title

**display** — Display strings and values of scalar expressions

Description

display displays strings and values of scalar expressions. display produces output from the programs that you write.

Syntax

where displayDirective is

"double-quoted string"

"compound double-quoted string",

[%%fmt] [ = ] exp

as {text|txt|result|error|input}

in smcl

_asis

_skip(#)

_column(#)

_newline[(#)]

_continue

_dup(#)

_request(macname)

_char(#)

,,

157
Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Styles
- display used with quietly and noisily
- Columns
- display and SMCL
- Displaying variable names
- Obtaining input from the terminal

Introduction

Interactively, display can be used as a substitute for a hand calculator; see [R] display. You can type things such as display 2+2.

display’s display_directives are used in do-files and programs to produce formatted output. The directives are

```
"double-quoted string"       displays the string without the quotes
'"compound double-quoted string"'       displays the string without the outer quotes;
                                        allows embedded quotes
[ '%fnt ] [ * ] exp        allows results to be formatted;
                                see [U] 12.5 Formats: Controlling how data are displayed
as style                sets the style (“color”) for the directives that follow;
                                        there may be more than one as style per display
in smcl                 switches from _asis mode to smcl mode
_asis               switches from smcl mode to _asis mode
_skip(#)               skips # columns
_column(#)             skips to the #th column
_newline              goes to a new line
_newline(#)            skips # lines
_continue             suppresses automatic newline at end of display command
_dup(#)               repeats the next directive # times
_request(macname)      accepts input from the console and places
                        it into the macro macname
_char(#)               displays the character for ASCII and extended ASCII code #,
                        where # > 127 is treated as a Latin1-encoded character
                        and will be converted to the corresponding UTF-8 character
,                     displays one blank between two directives
,,                    places no blanks between two directives
```
Example 1

Here is a nonsense program called silly that illustrates the directives:

```
. program list silly
silly:
  1.    set obs 10
  2.    gen myvar=runiform()
  3.    di as text _dup(59) "-"
  4.    di "hello, world"
  5.    di \%-59s "This is centered"
  6.    di "myvar[1] = " as result myvar[1]
  9.    di "This" _newline _col(5) "That" _newline _col(10) "What"
 10.   di ""She said, "Hello""
 11.   di substr("abcI can do string expressionsXYZ",4,27)
 12.   di _char(65) _char(83) _char(67) _char(73) _char(73)
 13.   di _dup(59) "-" " (good-bye)"
```

Here is the result of running it:

```
. silly
number of observations (_N) was 0, now 10
-----------------------------------------------------------
hello, world
This is centered
myvar[1] = .13698408
myvar[1]/myvar[2] = 0.2130
This
That
What
She said, "Hello"
I can do string expressions
ASCII
----------------------------------------------------------- (good-bye)
```

Styles

Stata has four styles: text (synonym txt), result, error, and input. Typically, these styles are rendered in terms of color,

- text = black
- result = black and bold
- error = red
- input = black and bold

or, at least, that is the default in the Results window when the window has a white background. On a black background, the defaults are

- text = green
- result = yellow
- error = red
- input = white
In any case, users can reset the styles by selecting Edit > Preferences > General Preferences in Windows or Unix(GUI) or by selecting Preferences > General Preferences in Mac.

The display directives as text, as result, as error, and as input allow you, the programmer, to specify in which rendition subsequent items in the display statement are to be displayed. So if a piece of your program reads

```stata
quietly summarize mpg
display as text "mean of mpg = " as result r(mean)
```

what might be displayed is

```
mean of mpg = 21.432432
```

where, above, our use of boldface for the 21.432432 is to emphasize that it would be displayed differently from the “mean of mpg =” part. In the Results window, if we had a black background, the “mean of mpg =” part would be in green and the 21.432432 would be in yellow.

You can switch back and forth among styles within a display statement and between display statements. Here is how we recommend using the styles:

**as result** should be used to display things that depend on the data being used. For statistical output, think of what would happen if the names of the dataset remained the same but all the data changed. Clearly, calculated results would change. That is what should be displayed as result.

**as text** should be used to display the text around the results. Again think of the experiment where you change the data but not the names. Anything that would not change should be displayed as text. This will include not just the names but also table lines and borders, variable labels, etc.

**as error** should be reserved for displaying error messages. as error is special in that it not only displays the message as an error (probably meaning that the message is displayed in red) but also forces the message to display, even if output is being suppressed. (There are two commands for suppressing output: quietly and capture. quietly will not suppress as error messages but capture will, the idea being that capture, because it captures the return code, is anticipating errors and will take the appropriate action.)

**as input** should never be used unless you are creating a special effect. as input (white on a black background) is reserved for what the user types, and the output your program is producing is by definition not being typed by the user. Stata uses as input when it displays what the user types.

### display used with quietly and noisily

display’s output will be suppressed by quietly at the appropriate times. Consider the following:

```
. program list example1
example1:
  1. di "hello there"
. example1
hello there
. quietly example1
```

The output was suppressed because the program was run `quietly`. Messages displayed `as error`, however, are considered error messages and are always displayed:

```
. program list example2
example2:
  1.    di as error "hello there"
. example2
hello there
. quietly example2
hello there
```

Even though the program was run `quietly`, the message `as error` was displayed. Error messages should always be displayed `as error` so that they will always be displayed at the terminal.

Programs often have parts of their code buried in `capture` or `quietly` blocks. Displays inside such blocks produce no output:

```
. program list example3
example3:
  1. quietly {
  2.       display "hello there"
  3.   }
. example3
  
```

If the `display` had included `as error`, the text would have been displayed, but only error output should be displayed that way. For regular output, the solution is to precede the `display` with `noisily`:

```
. program list example4
example4:
  1. quietly {
  2.       noisily display "hello there"
  3.   }
. example4
hello there
```

This method also allows Stata to correctly treat a `quietly` specified by the caller:

```
. quietly example4
  
```

Despite its name, `noisily` does not really guarantee that the output will be shown—it restores the output only if output would have been allowed at the instant the program was called.

For more information on `noisily` and `quietly`, see `[P] quietly`.

**Columns**

`display` can move only forward and downward. The directives that take a numeric argument allow only nonnegative integer arguments. It is not possible to back up to make an insertion in the output.
display and SMCL

Stata Markup and Control Language (SMCL) is Stata’s output formatter, and all Stata output passes through SMCL. See [P smcl] for a description. All the features of SMCL are available to display and so motivate you to turn to the SMCL section of this manual.

In our opening silly example, we included the line

    
    di as text _dup(59) "-"

That line would have better read

    di as text "{hline 59}"

The first display produces this:

-----------------------------------------------------------

and the second produces this:

-----------------------------------------------

It was not display that produced that solid line—display just displayed the characters \{hline 59\}. Output of Stata, however, passes through SMCL, and SMCL interprets what it hears. When SMCL heard \{hline 59\}, SMCL drew a horizontal line 59 characters wide.

SMCL has many other capabilities, including creating clickable links in your output that, when you click on them, can even execute other Stata commands.

If you carefully review the SMCL documentation, you will discover many overlap in the capabilities of SMCL and display that will lead you to wonder whether you should use display’s capabilities or SMCL’s. For instance, in the section above, we demonstrated the use of display’s \_column() feature to skip forward to a column. If you read the SMCL documentation, you will discover that SMCL has a similar feature, \{col\}. You can type

    display "Stuff" \_column(9) "More Stuff"

or you can type

    display "Stuff{col 9}More Stuff"

So, which should you type? The answer is that it makes no difference and that when you use display’s \_column() directive, display just outputs the corresponding SMCL \{col\} directive for you. This rule generalizes beyond \_column(). For instance,

    display as text "hello"

and

    display \{text}hello"

are equivalent. There is, however, one important place where display and SMCL are different:

    display as error "error message"
is not the same as

display "{error}error message"

Use display as error. The SMCL {error} directive sets the rendition to that of errors, but it does not tell Stata that the message is to be displayed, even if output is otherwise being suppressed. display as error both sets the rendition and tells Stata to override output suppression if that is relevant.

⚠️ Technical note

All Stata output passes through SMCL, and one side effect of that is that open and close brace characters, { and }, are treated oddly by display. Try the following:

display as text "{1, 2, 3}"
{1, 2, 3}

The result is just as you expect. Now try

display as text "{result}"

The result will be to display nothing because {result} is a SMCL directive. The first displayed something, even though it contained braces, because {1, 2, 3} is not a SMCL directive.

You want to be careful when displaying something that might itself contain braces. You can do that by using display’s _asis directive. Once you specify _asis, whatever follows in the display will be displayed exactly as it is, without SMCL interpretation:

display as text _asis "{result}"  
{result}

You can switch back to allowing SMCL interpretation within the line by using the in smcl directive:

display as text _asis "{result}" in smcl "is a {bf:smcl} directive"  
{result} is a smcl directive

Every display command in your program starts off in SMCL mode.

Displaying variable names

Let’s assume that a program we are writing is to produce a table that looks like this:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>displ</td>
<td>74</td>
<td>197.2973</td>
<td>91.83722</td>
<td>79</td>
<td>425</td>
</tr>
</tbody>
</table>

Putting out the header in our program is easy enough:

di as text " Variable {c |} Obs" /*
*/_col(37) "Mean Std. Dev. Min Max"
di as text "{hline 13}{c +}{hline 53}"

We use the SMCL directive {hline} to draw the horizontal line, and we use the SMCL characters {c |} and {c +} to output the vertical bar and the “plus” sign where the lines cross.

Now let’s turn to putting out the rest of the table. Variable names can be of unequal length and can even be long. If we are not careful, we might end up putting out something that looks like this:
If it were not for the too-long variable name, we could avoid the problem by displaying our lines with something like this:

```stata
display as text %12s "'vname'" " {c |} */
*/ %8.0g 'n' " " /*
*/ %9.0g 'mean' " " %9.0g 'sd' " " /*
*/ %9.0g 'min' " " %9.0g 'max'
```

What we are imagining here is that we write a subroutine to display a line of output and that the display line above appears in that subroutine:

```stata
program output_line
    args vname n mean sd min max
    display as text %12s abbrev("'vname'",12) " {c |}" */
    */ %8.0g 'n' " " /*
    */ %9.0g 'mean' " " %9.0g 'sd' " " /*
    */ %9.0g 'min' " " %9.0g 'max'
end
```

In our main routine, we would calculate results and then just call `output_line` with the variable name and results to be displayed. This subroutine would be sufficient to produce the following output:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>miles_per_gallon</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>displacement</td>
<td>74</td>
<td>197.2973</td>
<td>91.83722</td>
<td>79</td>
<td>425</td>
</tr>
</tbody>
</table>

The short variable name `weight` would be spaced over because we specified the `%12s` format. The right way to handle the `miles_per_gallon` variable is to display its abbreviation with Stata's `abbrev()` function:

```stata
program output_line
    args vname n mean sd min max
    display as text %12s abbrev("'vname'",12) " {c |}" */
    */ %8.0g 'n' " " /*
    */ %9.0g 'mean' " " %9.0g 'sd' " " /*
    */ %9.0g 'min' " " %9.0g 'max'
end
```

With this improved subroutine, we would get the following output:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>miles_per_~n</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>displacement</td>
<td>74</td>
<td>197.2973</td>
<td>91.83722</td>
<td>79</td>
<td>425</td>
</tr>
</tbody>
</table>

The point of this is to persuade you to learn about and use Stata's `abbrev()` function. `abbrev("'vname'",12)` returns `vname` abbreviated to 12 characters.
If we now wanted to modify our program to produce the following output,

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>miles_per_~n</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>displacement</td>
<td>74</td>
<td>197.2973</td>
<td>91.83722</td>
<td>79</td>
<td>425</td>
</tr>
</tbody>
</table>

all we would need to do is add a display at the end of the main routine that reads

```plaintext
    di as text "{hline 13}{c BT}{hline 53}"
```

Note the use of \{c BT\}. The characters that we use to draw lines in and around tables are summarized in \[P\] smcl.

Technical note

Much of the output of Stata’s official commands and of user-written commands is formatted to look good in a Results window that is 80 display columns wide. If you write a Stata program that you want to share with others, we recommend that you design it such that its output will fit in an 80-column-wide Results window. The `abbrev()` function described above is useful for abbreviating variable names such that output tables fit within 80 columns.

Your program can determine the current width of the Results window by checking the value of `c(linesize)`. Some Stata commands, such as official estimation commands that output a coefficient table, use the value of `c(linesize)` to determine by how much, if at all, they need to abbreviate variable names.

We can modify the `output_line` program above to respect `c(linesize)`. For every column the Results window is wider than 80, we can allow our variable name abbreviation to be one character longer. If the Results window is 100 or more columns wide, we may not need to abbreviate variable names at all, because the maximum length of a variable name is 32 characters, and we were already able to display 12 characters of the variable name at a line size of 80. Note that if your variable names contain Unicode characters, some of those characters may occupy two display columns. See \[U\] 12.4.2.2 Displaying Unicode characters.

```plaintext
    program output_line
    args vname n mean sd min max
    if (c(linesize) >= 100)
        local abname = "'vname'
    else if (c(linesize) > 80)
        local abname = abbrev("'vname'", 12+(c(linesize)-80))
    else
        local abname = abbrev("'vname'", 12)
    local abname = abbrev("'vname'",12)
    display as text %12s "'abname'" " |" /*
    */ as result   /*
    */ %8.0g 'n' " " /*
    */ %9.0g 'mean' " " %9.0g 'sd' " " /*
    */ %9.0g 'min' " " %9.0g 'max'
end
```
Technical note

Let’s now consider outputting the table in the form

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>miles_per_n</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>displacement</td>
<td>74</td>
<td>197.2973</td>
<td>91.83722</td>
<td>79</td>
<td>425</td>
</tr>
</tbody>
</table>

where the boldfaced entries are clickable and, if you click on them, the result is to execute `summarize` followed by the variable name. We assume that you have already read [P] smcl and so know that the relevant SMCL directive to create the link is `{stata}`, but continue reading even if you have not read [P] smcl.

The obvious fix to our subroutine would be simply to add the `{stata}` directive, although to do that we will have to store `abbrev("'vname',12)` in a macro so that we can refer to it:

```
program output_line
    args vname n mean sd min max
    local abname = abbrev("'vname',12)
    display as text %12s "{stata summarize 'vname':'abname'}" /*
        */ "{c |}" /*
        */ as result /*
        */ %8.0g 'n' " " /*
        */ %9.0g 'mean' " " %9.0g 'sd' " " /*
        */ %9.0g 'min' " " %9.0g 'max'
end
```

The SMCL directive `{stata summarize 'vname':'abname'}` says to display `abname` as clickable, and, if the user clicks on it, to execute `summarize 'vname'`. We used the abbreviated name to display and the unabbreviated name in the command.

The one problem with this fix is that our table will not align correctly because `display` does not know that “{stata summarize 'vname':'abname'” displays only ‘abname’. To display, the string looks long and is not going to fit into a %12s field. The solution to that problem is

```
program output_line
    args vname n mean sd min max
    local abname = abbrev("'vname',12)
    display as text "{ralign 12:{stata summarize 'vname':'abname'}}" /*
        */ "{c |}" /*
        */ as result /*
        */ %8.0g 'n' " " /*
        */ %9.0g 'mean' " " %9.0g 'sd' " " /*
        */ %9.0g 'min' " " %9.0g 'max'
end
```

The SMCL `{ralign #:text}` macro right-aligns `text` in a field 12 wide and so is equivalent to %12s. The `text` that we are asking be aligned is “{stata summarize 'vname':'abname'””, but SMCL understands that the only displayable part of the string is ‘abname’ and so will align it correctly.

If we wanted to duplicate the effect of a %-12s format by using SMCL, we would use `{lalign 12:text}`.
Obtaining input from the terminal

display’s _request(macname) option accepts input from the console and places it into the macro macname. For example,

. display "What is Y? " _request(yval)
What is Y? i don’t know
. display "$yval"
i don’t know

If yval had to be a number, the code fragment to obtain it might be

global yval "junk"
capture confirm number $yval
while _rc!=0 {
    display "What is Y? " _request(yval)
capture confirm number $yval
}

You will typically want to store such input into a local macro. Local macros have names that really begin with a ‘:_’:

local yval "junk"
capture confirm number ‘yval’
while _rc!=0 {
    display "What is Y? " _request(_yval)
capture confirm number ‘yval’
}

**Description**

Dynamic tags are instructions used by Stata’s dynamic documents commands, `dyndoc` and `dyntext`, to perform certain actions, such as run a block of Stata code, insert the result of a Stata expression in text, export a Stata graph to an image file and include a link to the image file, etc.

**Remarks**

Remarks are presented under the following headings:

- **Descriptions of dynamic tags**
- Version control
- Execute and include output from a block of Stata code
- Include strings and values of scalar expressions in text
- Export and include a Stata graph
- Include a text file
- Disable dynamic text processing
- Skip contents based on condition
- Remove contents

**Descriptions of dynamic tags**

Here is a list of available dynamic tags and a short description for each. The tag may be abbreviated; the minimum abbreviation is indicated by the underlined letters.

<table>
<thead>
<tr>
<th>Dynamic tags</th>

<tr>
<td><code>&lt;/dd_skip_end&gt;</code></td>
<td>end <code>&lt;dd_skip_if&gt;</code> block</td>
</tr>
</tbody>
</table>
Some tags must start at the beginning of a line, and the text in the same line after the tag is simply ignored. Other tags can be written in the middle of a line. The following table lists the required position in text for all tags.

<table>
<thead>
<tr>
<th>Dynamic tags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;&lt;dd_version&gt;&gt;</td>
<td>beginning of a line, recommended at the start of a file</td>

</tr>
<tr>
<td>&lt;&lt;dd_skip_end&gt;&gt;</td>
<td>beginning of a line</td>
</tr>
</tbody>
</table>

Tags can have attributes. Attributes are modifiers of a tag’s behavior. Attributes can be repeated, and the last one will take effect. For example, if you specify <<dd_do: commands nocommands>>, the commands will not be displayed because the attribute nocommands supersedes the previously specified attribute commands. This is useful when you experiment with behavior of attributes for the best output. Some attributes have values; for example, graphname() requires the name of the graph to be exported. If a tag has only one attribute and that attribute requires a value, then the attribute name is omitted and only the value is required; for example, dd_version tag is used as <<dd_version: an integer number>>.

**Version control**

<<dd_version: version_number>>

The <<dd_version>> tag specifies the minimum version required to convert the source file. The version number is independent of Stata’s version command. The tag must be at the beginning of a new line. We recommend that the tag be placed at the beginning of the srcfile.

The current version is 1, and it is introduced as of the release of Stata 15. The current version number is also stored in c(dyndoc_version).
Execute and include output from a block of Stata code

```
<<dd_do: attribute>>
block of Stata code . . .
</dd_do>>
```

The `<<dd_do>>` tag runs the block of Stata code, replacing the lines between `<<dd_do>>` and `</dd_do>>` with Stata output. Both the start tag `<<dd_do>>` and the end tag `</dd_do>>` must be at the beginning of new lines.

<table>
<thead>
<tr>
<th>attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quietly</td>
<td>suppress all output</td>
</tr>
<tr>
<td>nocommands</td>
<td>suppress printing of command</td>
</tr>
<tr>
<td>nooutput</td>
<td>suppress command output</td>
</tr>
<tr>
<td>noprompt</td>
<td>suppress the dot prompt</td>
</tr>
</tbody>
</table>

Include strings and values of scalar expressions in text

```
<<dd_display: display_directive>>
```

The `<<dd_display>>` tag executes Stata’s `display` command and then replaces the tag with its output. The tag cannot contain a line break or `>>`. Use `>>` instead if you need to include `>>` in the `display_directive`.

The `<<dd_display>>` tag can be used multiple times inside a line of text. For example, we want to display the circumference of a circle of radius 1 up to the two digits after the decimal. Instead of computing the number and then copying and pasting the result into the text, we can write

```
2*1*<<dd_display:%4.2f c(pi)>> = <<dd_display:%4.2f 2*1*c(pi)>>
```

which produces

```
2*1*3.14 = 6.28
```
Export and include a Stata graph

```<dd_graph: attribute>>
```

The `<<dd_graph>>` tag exports a Stata graph and then includes a link to the exported image file in the target file.

<table>
<thead>
<tr>
<th>attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>saving(filename)</code></td>
<td>export graph to <code>filename</code></td>
</tr>
<tr>
<td><code>replace</code></td>
<td>replace the file if it already exists</td>
</tr>
<tr>
<td><code>graphname(name)</code></td>
<td>name of graph to be exported</td>
</tr>
<tr>
<td><code>svg</code></td>
<td>export graph as SVG</td>
</tr>
<tr>
<td><code>png</code></td>
<td>export graph as PNG</td>
</tr>
<tr>
<td><code>pdf</code></td>
<td>export graph as PDF</td>
</tr>
<tr>
<td><code>eps</code></td>
<td>export graph as EPS</td>
</tr>
<tr>
<td><code>ps</code></td>
<td>export graph as PS</td>
</tr>
<tr>
<td><code>html</code></td>
<td>output an HTML link</td>
</tr>
<tr>
<td><code>markdown</code></td>
<td>output a Markdown link; default is html</td>
</tr>
<tr>
<td><code>pathonly</code></td>
<td>output the path of the file; default is html</td>
</tr>
<tr>
<td><code>alt(text)</code></td>
<td>alternative text for the graph; ignored if pathonly in effect</td>
</tr>
<tr>
<td><code>height(#)</code></td>
<td>height in pixels of the graph in HTML; ignored if markdown or pathonly in effect</td>
</tr>
<tr>
<td><code>width(#)</code></td>
<td>width in pixels of the graph in HTML; ignored if markdown or pathonly in effect</td>
</tr>
<tr>
<td><code>relative</code></td>
<td>use file path relative to the <code>targetfile</code> path specified in <code>dyndoc</code> or <code>dyntext</code>; this is the default</td>
</tr>
<tr>
<td><code>absolute</code></td>
<td>use absolute path in the link; default is relative</td>
</tr>
<tr>
<td><code>basepath(path)</code></td>
<td>use <code>path</code> as base directory where graph files will be exported; default is the current working directory if it is not specified</td>
</tr>
<tr>
<td><code>nourlencode</code></td>
<td>do not encode the path to a percent-encoded URL; ignored if html or markdown in effect</td>
</tr>
</tbody>
</table>

If `graphname(name)` is not specified, the topmost graph is used. You can use the default name “Graph” to export the graph without the name.

For paths specified in the `saving()` or `basepath()` attributes, a single backslash (\) is interpreted as an escape character rather than as the directory separator character. When working on Windows, we recommend using a forward slash (/) as the directory separator character (for example, C:/mypath/myfile), or you must use a double backslash (for example, C:\\mypath\\myfile).

If `saving(filename)` is not specified, a filename will be constructed based on the graph name.

If none of .svg, .png, or .pdf is specified, the `saving(filename)` is checked first; if the name specified in `saving(filename)` has the extension of .svg, .png, or .pdf, then the graph will be exported in the format corresponding to the extension. For example, the dynamic tag

```<dd_graph:saving(gr1.png) graphname(gr1)>
```

produces

```<img src="gr1.png">
```

Otherwise, the type .svg will be used as in

```<dd_graph:saving(gr1.pgg) graphname(gr1)>
```
which produces

\[
\text{If markdown is specified, a Markdown link will be produced. For example, the dynamic tag}
\]

\[
\text{produces}
\]

\[
\text{You may use pathonly if you want an HTML link with more attributes than \textit{html} or \textit{markdown}
\]

\[
\text{By default, the path is outputted as a percent-encoded URL. For example, the dynamic tag}
\]

\[
\text{produces}
\]

\[
\text{You may use \textit{nourlencode} to disable the encoding process as in}
\]

\[
\text{which produces}
\]

\[
\text{The \textit{dd_graph}}\textgreater\textless tag can be used inside a line of text.}
\]

\[
\textbf{Include a text file}
\]

\[
\text{The \textit{dd_include}}\textgreater\textless tag replaces the tag with the contents of the specified text file. The text
\]

\[
\text{file is included as is. The tag must be at the beginning of a new line.}
\]

\[
\textbf{Disable dynamic text processing}
\]

\[
\text{The \textit{dd_ignore}}\textgreater\textless and \textit{dd_ignore}}\textgreater\textless tag causes \textit{dyntext} and \textit{dyndoc}
\]

\[
\text{starting from the next line until the line right before a \textit{dd_ignore}}\textgreater\textless tag. Both the beginning and
\]

\[
\text{ending tags must be at the beginning of a line. The only tag it does not affect is the \textit{dd_remove}}\textgreater\textless tag.}
\]

\[
\textbf{Skip contents based on condition}
\]

\[
\text{or}
\]

\[
\text{or}
\]

\[
\text{or}
\]

\[
\text{or}
\]

\[
\text{or}
\]
<<dd_skip_if: Stata expression>> evaluates the *Stata expression*; if it evaluates to true (anything but 0), the lines before the next <<dd_skip_end>> are skipped. If there is a <<dd_skip_else>>, the lines before <<dd_skip_else>> are skipped, and the lines between <<dd_skip_else>> and <<dd_skip_end>> are processed as usual.

If the Stata expression evaluates to false (0), the lines before the next <<dd_skip_end>> are not skipped. If there is a <<dd_skip_else>>, the lines before <<dd_skip_else>> are not skipped, and the lines between <<dd_skip_else>> and <<dd_skip_end>> are skipped.

**Remove contents**

... <<dd_remove>>text to remove ...  
  lines of text to remove ...  
  text to remove ... <</dd_remove>> ...

The <<dd_remove>> and <</dd_remove>> tags remove all the contents between the two tags from the resulting target file. The tags can be used inside a line of text.

<<dd_remove>> is a postprocessing tag, which means it is processed after all other tags.

P markdown — Convert Markdown document to an HTML file
### dyndoc — Convert dynamic Markdown document to an HTML file

**Description**

`dyndoc` converts a dynamic Markdown document—a document containing both formatted text and Stata commands—to an output file in HTML format. Stata processes the Markdown text and Stata dynamic tags (see [P] dynamic tags) and creates the output HTML file. Markdown is a simple markup language with a formatting syntax based on plain text. It is easily converted to an output format such as HTML. Stata dynamic tags allow Stata commands, output, and graphs to be interleaved with Markdown text.

If you want to convert a Markdown document without Stata dynamic tags to an HTML document, see [P] markdown. If you want to convert a plain text file containing Stata dynamic tags to a plain text output file, see [P] dyntext.

**Syntax**

```
dyndoc srcfile [ arguments ] [ , options ]
```

`srcfile` is a plain text file containing Markdown-formatted text and Stata dynamic tags. `arguments` are stored in the local macros ‘1’, ‘2’, and so on for use in `srcfile`; see [U] 16.4.1 Argument passing.

You may enclose `srcfile` and `targetfile` in double quotes and must do so if they contain blanks or other special characters.

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>saving(targetfile)</code></td>
<td>specify the target HTML file to be saved</td>
</tr>
<tr>
<td>replace</td>
<td>replace the target HTML file if it already exists</td>
</tr>
<tr>
<td>hardwrap</td>
<td>replace hard wraps (actual line breaks) with the HTML tag <code>&lt;br&gt;</code></td>
</tr>
<tr>
<td>nomsg</td>
<td>suppress message of a link to <code>targetfile</code></td>
</tr>
<tr>
<td>nostop</td>
<td>do not stop when an error occurs</td>
</tr>
</tbody>
</table>

**Options**

`saving(targetfile)` specifies the target file to be saved. If `saving()` is not specified, the target filename is constructed using the source filename (`srcfile`) with the `.html` extension.

`replace` specifies that the target file be replaced if it already exists.

`hardwrap` specifies that hard wraps (actual line breaks) in the Markdown document be replaced with the HTML line break tag `<br>`.
nomsg suppresses the message that contains a link to the target file.

nostop allows the document to continue being processed even if an error occurs. By default, dyndoc stops processing the document if an error occurs. The error can be caused by either a malformed dynamic tag or by executing Stata code within the tag.

## Remarks and examples

A dynamic document contains both static narrative and dynamic tags. Dynamic tags are instructions for dyndoc to perform certain actions, such as run a block of Stata code, insert the result of a Stata expression in text, export a Stata graph to an image file and include a link to the image file, etc. Any changes in the data or in Stata will change the output as the document is created. The main advantages of using dynamic documents are

- results in the document come from executing commands instead of being copied from Stata and pasted into the document;
- no need to maintain parallel do-files; and
- any changes in data or in Stata are reflected in the final document when it is created.

### Example 1

Let us consider an example. Suppose that we have dyndoc_ex.txt with the following Markdown-formatted text that includes Stata dynamic tags.

```
begin dyndoc_ex.txt

Using Stata dynamic tags in a text file with the dyndoc command

Let us consider an example where we study the **mpg** and **weight** variables in **auto.dta**. In our examples below, we will first write the commands so that they will be displayed in our target HTML file. Then, we will write the commands so that Stata will process the Stata dynamic tags, displaying the results of the Stata commands in the target HTML file.

We first use the **sysuse** command to load the dataset and then describe the data using the **describe** command.

```stata
sysuse auto, clear
describe
```
```

This produces the following Stata results:

```stata
sysuse auto, clear
describe
```
```

Now, we want to check if **mpg** is always greater than 0 and less than 100. We use the **assert** command to perform the check. In this case, we do not want to include any output in the target HTML file, so we use the **quietly** attribute to modify the behavior of the **dd_do** Stata dynamic tag.

```stata
assert mpg > 0 & mpg < 100
```
If the data do not satisfy the conditions, **dyndoc** will fail with an error message, which will occur if we run the same **assert** command in a do-file. Next, we want to summarize the **weight** variable:

This produces the following in the target HTML file:

We want to use the minimum and maximum values of **weight** in a sentence. Instead of copying and pasting the numbers from the **summarize** output, we can use the **dd_display** Stata dynamic tag with the **r(min)** and **r(max)** stored results:

This produces the following in the target HTML file:

The **dd_display** dynamic tag uses Stata’s **display** command to evaluate expressions. It can be used as a calculator. For example, if we want to include the $$range = max - min$$ in a sentence, instead of calculating the number and then copying and pasting it, we can use

which produces the following in the target HTML file:

Now, we want to graph **mpg** and **weight** using a scatterplot. We use the **dd_do** tag with the **nooutput** attribute to generate the scatterplot first. The **nooutput** attribute leaves the command in the output only,
which generates a scatterplot of **mpg** and **weight** with 50% opacity color markers. 

Now, we want to export the graph to a file and include an image link to the file. 

This produces a graph of 400 pixels high.

---

Technical note

We use four tildes in a row, ~~~~, in our source file around parts of the document that we want to appear in plain text, such as Stata commands and output. Without the ~~~~, Stata’s output would be interpreted as HTML in the final document and would not look as it should.

You will notice that we used the <<dd_include>> dynamic tag to include the header.txt file. The header.txt file contains HTML code to include at the top of our target HTML file. It refers to the stmarkdown.css file, which is a stylesheet that defines how the HTML document is to be formatted. Both of these files and dyndoc_ex.txt are available at [http://www.stata-press.com/data/r15/markdown/](http://www.stata-press.com/data/r15/markdown/).

With these three files in our working directory, we generate the target HTML file in Stata by typing . dyndoc dyndoc_ex.txt
The HTML file dyndoc_ex.html is saved. Here is a portion of this file:

Using Stata dynamic tags in a text file with the dyndoc command

Let us consider an example where we study the mpg and weight variables in auto.dta. In our examples below, we will first write the commands so that they will be displayed in our target HTML file. Then, we will write the commands so that Stata will process the Stata dynamic tags, displaying the results of the Stata commands in the target HTML file.

We first use the sysuse command to load the dataset and then describe the data using the describe command.

```
<dd_do>
    sysuse auto, clear
    describe
</dd_do>
```

This produces the following Stata results:

```
. sysuse auto, clear
(1978 Automobile Data)
. describe

Contains data from /usr/local/stata15/ado/base/a/auto.dta
    obs:        74  1978 Automobile Data
    vars:       12  13 Apr 2016 17:45
    size: 3,182 (_dta has notes)

                   storage  display value
                      variable name    type format label        variable label
      make      str18     %9s     Make and Model
   price        int     %8.0gc  Price
      mpg         int     %8.0g  Mileage (mpg)
     rep78       int     %8.0g  Repair Record 1978
  headroom  float     %8.2f  Headroom (in.)
     trunk     int     %8.0g  Trunk space (cu. ft.)
   weight     int     %8.0gc  Weight (lbs.)
    length     int     %8.0g  Length (in.)
     turn     int     %8.0g  Turn Circle (ft.)
 displacement     int     %8.0g  Displacement (cu. in.)
     gear_ratio  float     %6.2f  Gear Ratio
   foreign     byte     %8.0g  origin
       Car type
```

Now, we want to check if mpg is always greater than 0 and less than 100. We use the assert command to perform the check. In this case, we do not want to include any output in the target HTML file, so we use the quietly attribute to modify the behavior of the dd_do Stata dynamic tag.

```
<dd_do:quietly>
    assert mpg > 0 & mpg < 100
</dd_do>
```

You can see the whole file at http://www.stata-press.com/data/r15/markdown/dyndoc_ex.html.
Technical note

Because *quietly* and *capture* suppress the results of the command from being produced, you should not use these prefix commands with Stata code to be converted by *dyndoc*.

Reference

Also see

- [P] *dynamic tags* — Dynamic tags for Markdown documents
- [P] *dyntext* — Process Stata dynamic tags in text file
- [P] *markdown* — Convert Markdown document to an HTML file
dyntext — Process Stata dynamic tags in text file

**Description**

dyntext converts a dynamic text file—a file containing both plain text and Stata commands—to an output file in text format. Stata processes the Stata dynamic tags (see [P] dynamic tags) in the dynamic text file and creates the output text file.

If you want to convert a dynamic text file to an HTML document, see [P] dyndoc. If you want to convert a Markdown document to an HTML document, see [P] markdown.

**Syntax**

```
dyntext srcfile [ arguments ], saving(targetfile) [ options ]
```

`srcfile` is a plain text file containing Stata dynamic tags. `srcfile` and `targetfile` may be any text format (.txt, .html, .do).

`arguments` are stored in the local macros ‘1’, ‘2’, and so on for use in `srcfile`; see [U] 16.4.1 Argument passing.

You may enclose `srcfile` and `targetfile` in double quotes and must do so if they contain blanks or other special characters.

**Options**

**saving(targetfile)** specifies the target file to be saved. saving() is required.

replace specifies that the target file be replaced if it already exists.

noremove specifies that ```<<dd_remove>>``` and ```</dd_remove>>``` dynamic tags should not be processed.

nostop specifies that the document continue being processed even if an error occurs. By default, dyndoc stops processing the document if an error occurs. The error can be caused either by a malformed dynamic tag or by executing Stata code within the tag.
Remarks and examples

A dynamic document contains both static narrative and dynamic tags. Dynamic tags are instructions for dyntext to perform certain actions, such as run a block of Stata code, insert the result of a Stata expression in text, export a Stata graph to an image file and include a link to the image file, etc. Any changes in the data or in Stata will change the output as the document is created. The main advantages of using dynamic documents are

- results in the document come from executing commands instead of being copied from Stata and pasted into the document;
- no need to maintain parallel do-files; and
- any changes in data or in Stata are reflected in the final document when it is created.

Example 1

Let us consider an example. Suppose that we have dyntext_ex.txt with the following text that includes Stata dynamic tags. Because we are writing in plain text, we use - to indicate Stata command names, variable names, etc.

```
begin dyntext_ex.txt

Using Stata dynamic tags in a text file with the -dyntext- command
==================================================================
Let us consider an example where we study the -mpg- and -weight- variables in -auto.dta-. In our examples below, we will first write the commands so that they will be displayed in our output text file. Then, we will write the commands so that Stata will process the Stata dynamic tags, displaying the results of the Stata commands in the output text file.

We first use the -sysuse- command to load the dataset and then describe the data using the -describe- command.

```

```
```
<<dd_do:quietly>>
assert mpg > 0 & mpg < 100
</dd_do>>

If the data do not satisfy the conditions, `-dyntext-` will fail with an error message, which will occur if we run the same `-assert-` command in a do-file.

Next, we want to summarize the `-weight-` variable:

<<dd_ignore>>
<<dd_do>>
summarize weight
</dd_do>>
</dd_ignore>>

This produces the following in the output text file:

<<dd_do>>
summarize weight
</dd_do>>

We want to use the minimum and maximum values of `-weight-` in a sentence. Instead of copying and pasting the numbers from the `-summarize-` output, we can use the `-dd_display-` Stata dynamic tag with the `-r(min)-` and `-r(max)-` stored results

<<dd_ignore>>
The variable weight has minimum value <<dd_display: %4.2f 'r(min)'>>
and has maximum value <<dd_display: %4.2f 'r(max)'>>.  
</dd_ignore>>

which produces the following in the output text file:

> The variable weight has minimum value <<dd_display: %4.2f 'r(min)'>>
and has maximum value <<dd_display: %4.2f 'r(max)'>>.  

The `-dd_display-` dynamic tag uses Stata’s `-display-` command to evaluate expressions. It can be used as a calculator. For example, if we want to include the range = max - min in a sentence, instead of calculating the number and then copying and pasting it, we can use

<<dd_ignore>>
The variable weight has range <<dd_display: %4.2f 'r(max)’-’r(min)’>>.  
</dd_ignore>>

which produces the following in the output text file:

> The variable weight has range <<dd_display: %4.2f ‘r(max)’-’r(min)’>>.
To generate the output file in Stata, we then type

```
.dynext dynext_ex.txt, saving(dyntext_res.txt)
```

which produces the following:

```
Using Stata dynamic tags in a text file with the -dyntext- command
==================================================================
Let us consider an example where we study the -mpg- and -weight- variables in -auto.dta-. In our examples below, we will first write the commands so that they will be displayed in our output text file. Then, we will write the commands so that Stata will process the Stata dynamic tags, displaying the results of the Stata commands in the output text file.

We first use the -sysuse- command to load the dataset and then describe the data using the -describe- command.

```
<<dd_do>>
sysuse auto, clear
describe
</dd_do>>
```

This produces the following Stata results:

```
. sysuse auto, clear
(1978 Automobile Data)
. describe
```

```
Contains data from /usr/local/stata15/ado/base/a/auto.dta
obs: 74 1978 Automobile Data
vars: 12 13 Apr 2016 17:45
size: 3,182 (_dta has notes)
----------------------------------------------------------------------------------
storage display value
variable name type format label variable label
----------------------------------------------------------------------------------
make str18 %-18s Make and Model
price int %8.0gc Price
mpg int %8.0g Mileage (mpg)
rep78 int %8.0g Repair Record 1978
headroom float %6.1f Headroom (in.)
trunk int %8.0g Trunk space (cu. ft.)
weight int %8.0gc Weight (lbs.)
length int %8.0g Length (in.)
turn int %8.0g Turn Circle (ft.)
displacement int %8.0g Displacement (cu. in.)
gear_ratio float %6.2f Gear Ratio
foreign byte %8.0g origin Car type
----------------------------------------------------------------------------------
Sorted by: foreign
```

Now, we want to check if -mpg- is always greater than 0 and less than 100. We use the -assert- command to perform the check. In this case, we do not want to include any output in the output text file, so we use the -quietly- attribute to modify the behavior of the -dd_do- Stata dynamic tag.

```
<<dd_do:quietly>>
assert mpg > 0 & mpg < 100
</dd_do>>
```
If the data do not satisfy the conditions, -dyntext- will fail with an error message, which will occur if we run the same -assert- command in a do-file.

Next, we want to summarize the -weight- variable:

    <<dd_do>>
    summarize weight
    <</dd_do>>

This produces the following in the output text file:

    . summarize weight
    Variable | Obs  Mean       Std. Dev.  Min      Max
    -------------+----------------------------------------
    weight | 74   3019.459  777.1936  1760      4840

We want to use the minimum and maximum values of -weight- in a sentence. Instead of copying and pasting the numbers from the -summarize- output, we can use the -dd_display- Stata dynamic tag with the -r(min)- and -r(max)- stored results

    The variable weight has minimum value <<dd_display: %4.2f 'r(min)'>>
    and has maximum value <<dd_display: %4.2f 'r(max)'>>. which produces the following in the output text file:

> The variable weight has minimum value 1760.00
and has maximum value 4840.00.

The -dd_display- dynamic tag uses Stata's -display- command to evaluate expressions. It can be used as a calculator. For example, if we want to include the range = max - min in a sentence, instead of calculating the number and then copying and pasting it, we can use

    The variable weight has range <<dd_display: %4.2f 'r(max)’-‘r(min)’>>. which produces the following in the output text file:

> The variable weight has range 3080.00.

Because quietly and capture suppress the results of the command from being produced, you should not use these prefix commands with Stata code to be converted by dyntext.

Description

- `ereturn local`, `ereturn scalar`, and `ereturn matrix` set the `e()` macros, scalars, and matrices other than `b`, `V`, and `Cns` returned by estimation commands. See [P] return for more discussion on returning results.

- `ereturn clear` clears the `e()` stored results.

- `ereturn list` lists the names and values of the macros and scalars stored in `e()`, and the names and sizes of the matrices stored in `e()` by the last estimation command.

- `ereturn post` clears all existing e-class results and stores the coefficient vector (`b`), variance–covariance matrix (`V`), and constraint matrix (`Cns`) in Stata’s system areas, making available all the postestimation features described in [U] 20 Estimation and postestimation commands. `b`, `V`, and `Cns` are optional for `ereturn post`; some commands (such as `factor`; see [MV] factor) do not have a `b`, `V`, or `Cns` but do set the estimation sample, `e(sample)`, and properties, `e(properties)`. You must use `ereturn post` before setting other `e()` macros, scalars, and matrices.

- `ereturn repost` changes the `b`, `V`, or `Cns` matrix (allowed only after estimation commands that posted their results with `ereturn post`) or changes the declared estimation sample or `e(properties)`. The specified matrices cease to exist after `post` or `repost`; they are moved into Stata’s system areas. The resulting `b`, `V`, and `Cns` matrices in Stata’s system areas can be retrieved by reference to `e(b)`, `e(V)`, and `e(Cns)`. `ereturn post` and `repost` deal with only the coefficient and variance–covariance matrices, whereas `ereturn matrix` is used to store other matrices associated with the estimation command.

- `ereturn display` displays or redisplays the coefficient table corresponding to results that have been previously posted using `ereturn post` or `repost`.

For a discussion of posting results with constraint matrices (`Cns` in the syntax diagram above), see [P] makecns, but only after reading this entry.
Syntax

Set macro returned by estimation command

\[
\texttt{ereturn local name} \ldots
\]

(see [P] \texttt{macro})

Set scalar returned by estimation command

\[
\texttt{ereturn scalar name} = \texttt{exp}
\]

Set matrix returned by estimation command

\[
\texttt{ereturn matrix name} \left[=\right] \texttt{matname} \left[\,, \text{copy}\right]
\]

Clear e() stored results

\[
\texttt{ereturn clear}
\]

List e() stored results

\[
\texttt{ereturn list} \left[\,, \text{all}\right]
\]

Store coefficient vector and variance–covariance matrix into e()

\[
\texttt{ereturn post} \left[\texttt{b} \left[\texttt{V} \left[\texttt{Cns}\right]\right]\right] \left[=\right] \texttt{weight} \left[\,, \texttt{depname(string)} \texttt{obs(#)} \texttt{dof(#)} \texttt{esample(varname)} \texttt{properties(string)} \texttt{buildfvinfo} \texttt{findomitted}\right]
\]

Change coefficient vector and variance–covariance matrix

\[
\texttt{ereturn repost} \left[\texttt{b} = \texttt{b}\right] \left[\texttt{V} = \texttt{V}\right] \left[\texttt{Cns} = \texttt{Cns}\right] \left[\texttt{weight}\right] \left[\,, \texttt{esample(varname)} \texttt{properties(string)} \texttt{buildfvinfo} \texttt{findomitted} \texttt{rename} \texttt{resize}\right]
\]

Display coefficient table

\[
\texttt{ereturn display} \left[\,, \texttt{eform(string)} \texttt{first neq(#)} \texttt{plus level(#)} \texttt{display_options}\right]
\]

where \texttt{name} is the name of the macro, scalar, or matrix that will be returned in \texttt{e(name)} by the estimation program; \texttt{matname} is the name of an existing matrix; \texttt{b} is a 1 \times p coefficient vector (matrix); \texttt{V} is a p \times p covariance matrix; and \texttt{Cns} is a c \times (p + 1) constraint matrix. \texttt{fweights}, \texttt{aweights}, \texttt{iweights}, and \texttt{pweights} are allowed; see [U] 11.1.6 \texttt{weight}. 
**Options**

- **copy** specified with `ereturn matrix` indicates that the matrix is to be copied; that is, the original matrix should be left in place.

- **all** specifies that hidden and historical stored results be listed along with the usual stored results. This option is seldom used. See `Using hidden and historical stored results` and `Programming hidden and historical stored results` under Remarks and examples of `[P] return` for more information. These sections are written in terms of `return list`, but everything said there applies equally to `ereturn list`.

- **depname(string)** specified with `ereturn post` supplies a name that should be that of the dependent variable but can be anything; that name is stored and added to the appropriate place on the output whenever `ereturn display` is executed.

- **obs(#)** specified with `ereturn post` supplies the number of observations on which the estimation was performed; that number is stored in `e(N)`.

- **dof(#)** specified with `ereturn post` supplies the number of (denominator) degrees of freedom that is to be used with $t$ and $F$ statistics and is stored in `e(df_r)`. This number is used in calculating significance levels and confidence intervals by `ereturn display` and by subsequent `test` commands performed on the posted results. If the option is not specified, normal ($Z$) and $\chi^2$ statistics are used.

- **esample(varname)** specified with `ereturn post` or `ereturn repost` gives the name of the 0/1 variable indicating the observations involved in the estimation. The variable is removed from the dataset but is available for use as `e(sample)`; see `[U] 20.7 Specifying the estimation subsample`. If the `esample()` option is not specified with `ereturn post`, it is set to all zeros (meaning no estimation sample). See `[P] mark` for details of the `marksample` command that can help create `varname`.

- **properties(string)** specified with `ereturn post` or `ereturn repost` sets the `e(properties)` macro. By default, `e(properties)` is set to `b V` if `properties()` is not specified.

- **buildfvinfo** specified with `ereturn post` or `ereturn repost` computes the $H$ matrix that postestimation commands `contrast`, `margins`, and `pwcompare` use for determining estimable functions.

- **findomitted** specified with `ereturn post` or `ereturn repost` adds the omit operator o. to variables in the column names corresponding to zero-valued diagonal elements of $e(V)$. This option is generally unnecessary but is useful when `_rmcoll` is not used before estimation.

- **rename** is allowed only with the `b = b` syntax of `ereturn repost` and tells Stata to use the names obtained from the specified `b` matrix as the labels for both the `b` and `V` estimation matrices. These labels are subsequently used in the output produced by `ereturn display`.

- **resize** is allowed only with `ereturn repost` and tells Stata that the replacements $b$, $V$, and $Cns$ have a different number of elements than the originals. This option implies `rename`.

- **eform(string)** specified with `ereturn display` indicates that the exponentiated form of the coefficients is to be output and that reporting of the constant is to be suppressed. `string` is used to label the exponentiated coefficients; see `[R] eform_option`.

- **first** requests that Stata display only the first equation and make it appear as if only one equation were estimated.

- **neq(#)** requests that Stata display only the first # equations and make it appear as if only # equations were estimated.
plus changes the bottom separation line produced by `ereturn display` to have a `+` symbol at the position of the dividing line between variable names and results. This is useful if you plan on adding more output to the table.

`level(#)`, an option of `ereturn display`, specifies the confidence level, as a percentage, of confidence intervals for the estimated parameters; see [U] 20.8 Specifying the width of confidence intervals.

display_options: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwwrap(#)`, `fwwrapon(style)`, `cformat(\%fmt)`, `pformat(\%fmt)`, `sformat(\%fmt)`, and `nolstretch`; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

- Estimation-class programs
- Setting individual estimation results
- Posting estimation coefficient and variance-covariance matrices
  - Single-equation models
  - Multiple-equation models
  - Single-equation models masquerading as multiple-equation models
- Setting the estimation sample
- Setting estimation-result properties
- Reposting results
- Minor details: The depname() and dof() options

For a summary of the `ereturn` command, see [P] return.

Estimation-class programs

After any estimation command, you can obtain individual coefficients and standard errors by using `b[]` and `se[]` (see [U] 13.5 Accessing coefficients and standard errors); list the coefficients by using `matrix list e(b)`; list the variance-covariance matrix of the estimators by using `matrix list e(V)` or in a table by using `estat vce` (see [R] estat vce); obtain the linear prediction and its standard error by using `predict` (see [R] predict); and test linear hypotheses about the coefficients by using `test` (see [R] test). Other important information from an estimation command can be obtained from the stored `e()` results. (For example, the estimation command name is stored in `e(cmd)`. The dependent variable name is stored in `e(depvar)`.) The `e()` results from an estimation command can be listed by using the `ereturn list` command. All of these features are summarized in [U] 20 Estimation and postestimation commands.

If you decide to write your own estimation command, your command can share all of these features as well. This is accomplished by posting the results you calculate to Stata. The basic outline of an estimation command is

```
program myest, eclass
    version 15.0
    if !replay() {
        syntax whatever [, whatever Level(cilevel)]
        marksample touse // see [P] mark
        perform any other parsing of the user's estimation request;
        local depn "dependent variable name"
        local nobs = number of observations in estimation
        tempname b V
        produce coefficient vector `b' and variance-covariance matrix `V'
        ereturn post `b' `V', obs(`nobs') depname(`depn') esample(`touse')
    }
```

This basic outline allows for the sharing of common features among estimation commands, providing flexibility and ease of use for users.
We will not discuss here how the estimates are formed; see [P] matrix for an example of programming linear regression, and see [R] ml for examples of programming maximum likelihood estimators. However the estimates are formed, our interest is in posting those results to Stata.

When programming estimation commands, remember to declare them as estimation commands by including the eclass option of program; see [U] 18 Programming Stata. If you do not declare your program to be eclass, Stata will produce an error if you use ereturn local, ereturn scalar, or ereturn matrix in your program. For more information about storing program results, see [P] return.

The estimation program definition statement—`program myest, eclass`—should also have included a properties() option, but we omitted it because 1) it is not necessary and 2) you might confuse it with ereturn’s properties() option.

There are two sets of properties associated with estimation commands: program properties and estimation-result properties. The first are set by the properties() option of the program definition statement. The second are set by ereturn’s properties() option. The first tell Stata’s prefix commands, such as stepwise and svy, whether they should work with this new estimation command. The second tell Stata’s postestimation commands, such as predict and test, whether they should work after this new estimation command.

The first is discussed in [P] program properties. The second will be discussed below.

**Technical note**

Notice the use of the replay() function in our estimation program example. This function is not like other Stata functions; see [FN] Programming functions. replay() simply returns 1 if the command line is empty or begins with a comma, and 0 otherwise. More simply: replay() indicates whether the command is an initial call to the estimation program (replay() returns 0) or a call to redisplay past estimation results (replay() returns 1).

In fact,

```stata
if !replay() {
    // initial call
```

is equivalent to

```stata
if trim("0") == "" | substr((trim("0"),1,1) == ",", {  
```

but is easier to read.

The ereturn local, ereturn scalar, ereturn matrix, ereturn clear, and ereturn list commands are discussed in Setting individual estimation results. The ereturn post, ereturn repost, and ereturn display commands are discussed in Posting estimation coefficient and variance–covariance matrices.
Setting individual estimation results

Stata’s estimation commands store the command name in the returned macro `e(cmd)` and store the name of the dependent variable in `e(depvar)`. Other macros and scalars are also stored. For example, the estimation sample size is stored in the returned scalar `e(N)`. The model and residual degrees of freedom are stored in `e(df_m)` and `e(df_r)`.

These `e()` macro and scalar results are stored using the `ereturn local` and `ereturn scalar` commands. Matrices may be stored using the `ereturn matrix` command. The coefficient vector `e(b)` and variance–covariance matrix `e(V)`, however, are handled differently and are stored using only the `ereturn post` and `ereturn repost` commands, which are discussed in the next section.

Example 1

Assume that we are programming an estimation command called `xyz` and that we have the dependent variable in `depname`, the estimation sample size in `nobs`, and other important information stored in other local macros and scalars. We also wish to store an auxiliary estimation matrix that our program has created called `lam` into the stored matrix `e(lambda)`. We would store these results by using commands such as the following in our estimation program:

```
... ereturn local depvar "depname"
ereturn scalar N = nobs
ereturn matrix lambda lam
...
ereturn local cmd "xyz"
```

The matrix given to the `ereturn matrix` command is removed, and the new `e()` matrix is then made available. For instance, in this example, we have the line

```
ereturn matrix lambda lam
```

After this line has executed, the matrix `lam` is no longer available for use, but you can instead refer to the newly created `e(lambda)` matrix.

The `e()` results from an estimation command can be viewed using the `ereturn list` command.

Example 2

We regress automobile weight on length and engine displacement by using the auto dataset.

```
. use http://www.stata-press.com/data/r15/auto
(1978 Automobile Data)
. regress weight length displ
```
erin — Post the estimation results

. ereturn list

scalars:
  e(N) = 74
  e(df_m) = 2
  e(df_r) = 71
  e(F) = 480.9907735088096
  e(r2) = .9312669232040125
  e(rmse) = 206.6067636285298
  e(mss) = 4106344.82961433
  e(rss) = 3030728.548737053
  e(r2_a) = .9293307801956748
  e(ll) = -497.9506459758983
  e(ll_0) = -597.0190609278627
  e(rank) = 3

macros:
  e(cmdline) : "regress weight length displ"
  e(title) : "Linear regression"
  e(marginsok) : "XB default"
  e(vce) : "ols"
  e(depvar) : "weight"
  e(cmd) : "regress"
  e(properties) : "b V"
  e(predict) : "regres_p"
  e(estat_cmd) : "regress_estat"

matrices:
  e(b) : 1 x 3
  e(V) : 3 x 3

functions:
  e(sample)

In addition to listing all the e() results after an estimation command, you can access individual e() results.

. display "The command is: 'e(cmd)'"," The command is: regress
. display "The adjusted R-squared is: 'e(r2_a)'", The adjusted R-squared is: .9293307801956748
. display "The residual sums-of-squares is: 'e(rss)'", The residual sums-of-squares is: 3030728.548737053
. matrix list e(V)

symmetric e(V)[3,3]
  length  displacement  _cons
  length  3.8983761
  displacement -.78935643  .22916272
  _cons -576.89342  103.13249  88646.064

. matrix list e(b)

  e(b)[1,3]
  length  displacement  _cons
  y1  22.917876  2.9327718  -1866.1807

For more information on referring to e() results, see [P] return.

The reference manuals’ entries for Stata’s estimation commands have a Stored results section describing the e() results that are returned by the command. If you are writing an estimation command, we recommend that you store the same kind of estimation results by using the same naming convention as Stata’s estimation commands. This is important if you want postestimation commands to work after your estimation command. See [U] 20 Estimation and postestimation commands and [P] return for details.
When programming your estimation command, you will want to issue either an `ereturn clear` command or an `ereturn post` command before you store any estimation results. The `ereturn clear` command clears all `e()` results. The `ereturn post` command, which is discussed in the next section, first clears all previous `e()` results and then performs the post.

We recommend that you postpone clearing past estimation results and setting new `e()` results until late in your program. If an error occurs early in your program, the last successful estimation results will remain intact. The best place in your estimation program to set the `e()` results is after all other calculations have been completed and before estimation results are displayed.

We also recommend that you store the command name in `e(cmd)` as your last act of storing results. This ensures that if `e(cmd)` is present, then all the other estimation results were successfully stored. Postestimation commands assume that if `e(cmd)` is present, then the estimation command completed successfully and all expected results were stored. If you stored `e(cmd)` early in your estimation command and the user pressed Break before the remaining `e()` results were stored, postestimation commands operating on the partial results will probably produce an error.

**Posting estimation coefficient and variance–covariance matrices**

The most important estimation results are the coefficient vector `b` and the variance–covariance matrix `V`. Because these two matrices are at the heart of most estimation commands, for increased command execution speed, Stata handles these matrices in a special way. The `ereturn post`, `ereturn repost`, and `ereturn display` commands work on these matrices. The `ereturn matrix` command discussed in the last section cannot be used to store or to post the `b` and `V` matrices.

**Single-equation models**

Before posting, the coefficient vector is stored as a $1 \times p$ matrix and the corresponding variance–covariance matrix as a $p \times p$ matrix. The names bordering the coefficient matrix and those bordering the variance–covariance matrix play an important role. First, they must be the same. Second, it is these names that tell Stata how the results link to Stata’s other features.

Estimation results come in two forms: those for single-equation models and those for multiple-equation models. The absence or presence of equation names in the names bordering the matrix (see [P] `matrix rownames`) tells Stata which form it is.

### Example 3

For instance, consider

```
. use http://www.stata-press.com/data/r15/auto
   (1978 Automobile Data)
. regress price weight mpg
   (output omitted)
. matrix b = e(b)
. matrix V = e(V)
. matrix list b
  b[1,3]    
  weight   mpg   _cons
  y1       1.7465592 -49.512221 1946.0687
. matrix list V
  symmetric V[3,3]
  weight   mpg   _cons
```
If these were our estimation results, they would correspond to a single-equation model because the names bordering the matrices have no equation names. Here we post these results:

```
. ereturn post b V
. ereturn display
```

|       | Coef. | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|-------|-------|-----------|-------|-------|----------------------|
| weight| 1.746559 | .6413538 | 2.72  | 0.006 | .4895288 3.003589   |
| mpg   | -49.51222 | 86.15604 | -.57  | 0.566 | -218.375 119.3505  |
| _cons | 1946.069  | 3597.05  | .54   | 0.588 | -5104.019 8996.156 |

Once the results have been posted, anytime the `ereturn display` command is executed, Stata will redisplay the coefficient table. Moreover, all of Stata’s other postestimation features work. For instance,

```
. test weight
   ( 1) weight = 0
   chi2( 1) = 7.42
   Prob > chi2 = 0.0065

. test weight=mpg/50
   ( 1) weight - .02*mpg = 0
   chi2( 1) = 4.69
   Prob > chi2 = 0.0303
```

If the user were to type `predict pred`, then `predict` would create a new variable based on

\[ 1.746559 \times \text{weight} - 49.51222 \times \text{mpg} + 1946.069 \]

except that it would carry out the calculation by using the full, double-precision values of the coefficients. All determinations are made by Stata on the basis of the names bordering the posted matrices.

---

**Multiple-equation models**

If the matrices posted using the `ereturn post` or `ereturn repost` commands have more than one equation name, the estimation command is treated as a multiple-equation model.

**Example 4**

Consider the following two matrices before posting:

```
. matrix list b
b[1,6]
      price:      price:      price:     displacem-t:    displacem-t:     displacem-t:
      weight    mpg       _cons    weight     foreign
y1  1.7417059    -50.31993  1977.9249    .09341608   -35.124241
      displacem-t:      displacem-t:      _cons
y1   -74.326413
```

The row and column names of the matrices include equation names. Here we post these matrices to Stata and then use the posted results:

```
. matrix list V

symmetric V[6,6]

    price: price: price: displacem-t: displacem-t: displacem-t:
    weight mpg _cons weight
price:weight .38775906
price:mpg 41.645165 6930.8263

. test [price]weight
   ( 1) [price]weight = 0
   chi2( 1) =  7.82
   Prob > chi2 = 0.0052

. test weight
   ( 1) [price]weight = 0
   ( 2) [displacement]weight = 0
   chi2( 2) = 164.51
   Prob > chi2 = 0.0000
```

Stata determined that this was a multiple-equation model because equation names were present. All of Stata’s equation-name features (such as those available with the `test` command) are then made available. The user could type `predict pred` to obtain linear predictions of the `[price]` equation (because `predict` defaults to the first equation) or type `predict pred, equation(displ)` to obtain predictions of the `[displ]` equation:

```
.0934161 weight - 35.12424 foreign - 74.32641
```
Single-equation models masquerading as multiple-equation models

Example 5

Sometimes, it may be convenient to program a single-equation model as if it were a multiple-equation model. This occurs when there are ancillary parameters. Think of linear regression: in addition to the parameter estimates, there is \( s \), which is an estimate of \( \sigma \), the standard error of the residual. This can be calculated on the side in that you can calculate \( \mathbf{b} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y} \) independently of \( s \) and then calculate \( s \) given \( \mathbf{b} \). Pretend that were not the case—think of a straightforward maximum likelihood calculation where \( s \) is just one more parameter (in most models, ancillary parameters and the coefficients must be solved for jointly). The right thing to do would be to give \( s \) its own equation:

```
.matrix list b
b[1,4]
    price: price: price: _anc:
    weight mpg _cons sigma
y1 1.7465592 -49.512221 1946.0687 2514

.matrix list V
symmetric V[4,4]
    price: price: price: _anc:
    weight mpg _cons sigma
price:weight .41133468
price:mpg 44.601659 7422.863
price:_cons -2191.9032 -292759.82 12938766
_anc:sigma 0 0 0 810000

. ereturn post b V
. ereturn display
```

|                | Coef. | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------------|-------|-----------|------|------|----------------------|
| price          |       |           |      |      |                      |
| weight         | 1.746559 | .6413538  | 2.72 | 0.006 | .4895288 3.003589    |
| mpg            | -49.51222 | 86.15604   | -0.57 | 0.566 | -218.375 119.3505   |
| _cons          | 1946.069 | 3597.05   | 0.54 | 0.588 | -5104.019 8996.156  |
| _anc           |       |           |      |      |                      |
| sigma          | 2514  | 900       | 2.79 | 0.005 | 750.0324 4277.968   |

Now consider the alternative, which would be simply to add \( s \) to the estimated parameters without equation names:

```
.matrix list b
b[1,4]
    weight mpg _cons sigma
y1 1.7465592 -49.512221 1946.0687 2514

.matrix list V
symmetric V[4,4]
    weight mpg _cons sigma
weight .41133468
mpg 44.601659 7422.863
_cons -2191.9032 -292759.82 12938766
sigma 0 0 0 810000

. ereturn post b V
```
This second solution is inferior because, if the user typed `predict pred`, then `predict` would attempt to form the linear combination:

\[ 1.746559 \text{ weight} - 49.51222 \text{ mpg} + 1946.069 + 2514 \sigma \]

There are only two possibilities, and neither is good: either \( \sigma \) does not exist in the dataset—which is to be hoped—and `predict` produces the error message “variable sigma not found”, or something called \( \sigma \) does exist, and `predict` goes on to form this meaningless combination.

On the other hand, if the parameter estimates are separated from the ancillary parameter (which could be parameters) by the equation names, the user can type `predict pred, equation(price)` to obtain a meaningful result. Moreover, the user can omit `equation(price)` partly because `predict` (and Stata’s other postestimation commands) defaults to the first equation.

We recommend that ancillary parameters be collected together and given their own equation and that the equation be called `_anc`.

### Setting the estimation sample

In our previous examples, we did not indicate the estimation sample as specified with the `esample(varname)` option. In general, you provide this either with your initial `ereturn post` command or with a subsequent `ereturn repost` command. Some postestimation commands automatically restrict themselves to the estimation sample, and if you do not provide this information, they will complain that there are no observations; see [U] 20.7 Specifying the estimation subsample. Also, users of your estimation command expect to use `if e(sample)` successfully in commands that they execute after your estimation command.

#### Example 6

Returning to our first example:

```stata
    . ereturn post b V
    . ereturn display
     (output omitted)
    . summarize price if e(sample)

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

does not produce what the user expects. Specifying the estimation sample with the `esample( )` option of `ereturn post` produces the expected result:
The `marksample` command (see [P] mark) is a useful programming command that aids in creating and setting up an estimation sample indicator variable, such as `estsamp`.

### Setting estimation-result properties

The `properties()` option of `ereturn post` and `repost` allows you to set `e(properties)`. By default, `ereturn post` sets `e(properties)` to `b V` when you supply a `b` and `V` argument. If you supply the `b`, but not the `V`, it defaults to `b`. If you do not supply the `b` and `V`, it defaults to being empty. Using the `properties()` option, you can augment or override the default setting. You are also free to use `ereturn local` to set `e(properties)`.

`e(properties)` is used as a signal to postestimation commands. A `b` in `e(properties)` is a signal that the `e(b)` returned matrix can be interpreted as a coefficient vector. A `V` in `e(properties)` indicates that `e(V)` can be interpreted as a VCE matrix. An `e(properties)` containing `eigen` indicates that the estimation command has placed eigenvalues in `e(Ev)` and eigenvectors in `e(L)`. A command, such as `screeplot` (see [MV] screeplot), that plots the eigenvalues and can be used as a postestimation command looks to see if `eigen` is found in `e(properties)`. If so, it then looks for `e(Ev)` to contain the eigenvalues.

### Example 7

We demonstrate by interactively posting a `b` vector without posting a `V` matrix. Even without a `V` matrix, the available information provided by `b` is used appropriately.

```stata
use http://www.stata-press.com/data/r15/auto, clear
matrix b=(2,-1)
matrix colnames b = turn trunk
ereturn post b
ereturn display
des
predict myxb, xb
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>74</td>
<td>6165.257</td>
<td>2949.496</td>
<td>3291</td>
<td>15906</td>
</tr>
</tbody>
</table>
. list turn trunk myxb in 1/4

<table>
<thead>
<tr>
<th></th>
<th>40</th>
<th>11</th>
<th>69</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.</td>
<td>40</td>
<td>11</td>
<td>69</td>
</tr>
<tr>
<td>3.</td>
<td>35</td>
<td>12</td>
<td>58</td>
</tr>
<tr>
<td>4.</td>
<td>40</td>
<td>16</td>
<td>64</td>
</tr>
</tbody>
</table>

The estimation table produced by `ereturn display` omits the standard errors, tests, and confidence intervals because they rely on having a VCE matrix. `predict` with the `xb` option produces the linear predictions. If you tried to use the `stdp` option of `predict`, you would get an error message indicating that the requested action was not valid.

The `has_eprop()` programmer’s function is useful for determining if `e(properties)` contains a particular property; see [FN] Programming functions.

Technical note

Do not confuse the properties set with the `properties()` option of `ereturn post` and `ereturn repost`, which are placed in `e(properties)` and used by postestimation commands, with the `properties()` option of the `program` command; see [P] program. The properties set by `program` indicate to other programs before the command is executed that certain features have been implemented, for example, the `svyr` property indicates to the `svy` prefix command that the requirements to use the `vce(linearized)` variance estimation method have been satisfied. On the other hand, the properties set by `ereturn` are for use after the program has run and may depend on the data and options of the program.

Reposting results

In certain programming situations, only a small part of a previous estimation result needs to be altered. `ereturn repost` allows us to change five parts of an estimation result that was previously posted with `ereturn post`. We can change the coefficient vector, the variance–covariance matrix, and the declared estimation sample by using the `esample()` option; we can change the declared properties by using the `properties()` option; and we can change the variable names for the coefficients by using the `rename` option. A programmer might, for instance, simply replace the variance–covariance matrix provided by a previous `ereturn post` with a robust covariance matrix to create a new estimation result.

Sometimes a programmer might preserve the data, make major alterations to the data (using `drop`, `reshape`, etc.) to perform needed computations, post the estimation results, and then finally restore the data. Here, when `ereturn post` is called, the correct estimation sample indicator variable is unavailable. `ereturn repost` with the `esample()` option allows us to set the estimation sample without changing the rest of our posted estimation results.
Example 8

For example, inside an estimation command program, we might have

```bash
...  
ereturn post b V
...  
ereturn repost, esample(estsamp)
...  
```

Technical note

`ereturn repost` may be called only from within a program that has been declared an estimation class program by using the `eclass` option of the `program` statement. The same is not true of `ereturn post`. We believe that the only legitimate uses of `ereturn repost` are in a programming context. `ereturn post`, on the other hand, may be important for some non-e-class programming situations.

Minor details: The depname() and dof() options

Single-equation models may have one dependent variable; in those that do, you should specify the identity of this one dependent variable in the `depname()` option with `ereturn post`. The result is simply to add a little more labeling to the output.

If you do not specify the `dof(#)` option at the time of posting or set `e(df_r)` equal to the degrees of freedom, normal (Z) statistics will be used to calculate significance levels and confidence intervals on subsequent `ereturn display` output. If you do specify `dof(#)` or set `e(df_r)` equal to #, t statistics with # degrees of freedom will be used. Similarly, if you did not specify `dof(#)` or set `e(df_r)`, any subsequent `test` commands will present a $\chi^2$ statistic; if you specify `dof(#)` or set `e(df_r)`, subsequent `test` commands will use the $F$ statistic with # denominator degrees of freedom.

Example 9

Let’s add the dependent variable name and degrees of freedom to example 3.

```bash
. ereturn post b V, depname(price) dof(71)
. ereturn display
```

|       | Coef.     | Std. Err. | t       | P>|t|   | [95% Conf. Interval] |
|-------|-----------|-----------|---------|-------|---------------------|
| weight| 1.746559  | .6413538  | 2.72    | 0.008 | .467736             |
| mpg   | -49.51222 | 86.15604  | -0.57   | 0.567 | -221.3025           |
| _cons | 1946.069  | 3597.05  | 0.54    | 0.590 | -5226.245           |

Note the addition of the word `price` at the top of the table. This was produced because of the `depname(price)` option specification. Also $t$ statistics were used instead of normal (Z) statistics because the `dof(71)` option was specified.
Stored results

**ereturn post** stores the following in e():

Scalars
- \( e(N) \): number of observations
- \( e(df_r) \): degrees of freedom, if specified

Macros
- \( e(wtype) \): weight type
- \( e(wexp) \): weight expression
- \( e(properties) \): estimation properties; typically \( b V \)

Matrices
- \( e(b) \): coefficient vector
- \( e(Cns) \): constraints matrix
- \( e(V) \): variance–covariance matrix of the estimators

Functions
- \( e(sample) \): marks estimation sample

**ereturn repost** stores the following in e():

Macros
- \( e(wtype) \): weight type
- \( e(wexp) \): weight expression
- \( e(properties) \): estimation properties; typically \( b V \)

Matrices
- \( e(b) \): coefficient vector
- \( e(Cns) \): constraints matrix
- \( e(V) \): variance–covariance matrix of the estimators

Functions
- \( e(sample) \): marks estimation sample

With **ereturn post**, all previously stored estimation results—e() items—are removed. **ereturn repost**, however, does not remove previously stored estimation results. **ereturn clear** removes the current e() results.

**ereturn display** stores the following in r():

Scalars
- \( r(level) \): confidence level of confidence intervals

Macros
- \( r(label#) \): label on the # coefficient, such as (base), (omitted), (empty), or (constrained)
- \( r(table) \): information from the coefficient table (see below)

**r(table)** contains the following information for each coefficient:

b: coefficient value
se: standard error
t/z: test statistic for coefficient
pvalue: observed significance level for t/z
ll: lower limit of confidence interval
ul: upper limit of confidence interval
df: degrees of freedom associated with coefficient
crit: critical value associated with t/z
eform: indicator for exponentiated coefficients

Title

**error** — Display generic error message and exit

<table>
<thead>
<tr>
<th>Description</th>
<th>Syntax</th>
<th>Remarks and examples</th>
<th>Also see</th>
</tr>
</thead>
</table>

**Description**

`error` displays the most generic form of the error message associated with expression and sets the return code to the evaluation of the expression. If expression evaluates to 0, `error` does nothing. Otherwise, the nonzero return code will force an `exit` from the program or `capture` block in which it occurs. `error` sets the return code to 197 if there is an error in using `error` itself.

**Syntax**

`error exp`

**Remarks and examples**

Remarks are presented under the following headings:

- **Introduction**
- **Summary**
- **Other messages**

**Introduction**

`error` is used in two ways inside programs. In the first case, you want to display a standard error message so that users can look up your message by using `search`:

```plaintext
if ('nvals'>100) error 134
```

According to [R] `search`, return code 134 is associated with the message “too many values”. During program development, you can verify that by typing the error command interactively:

```plaintext
    . error 134
too many values
    r(134);
```

Below we list the individual return codes so that you can select the appropriate one for use with `error` in your programs.

`error` is also used when you have processed a block of code in a `capture` block, suppressing all output. If anything has gone wrong, you want to display the error message associated with whatever the problem was:

```plaintext
capture {
    code continues
}
local rc=_rc
                  preserve return code from capture
cleanup code
error 'rc'
                  present error message and exit if necessary
code could continue
```

Usually, one hopes that the return code will be zero so that `error` does nothing.
You can interrogate the built-in variable \_rc to determine the type of error that occurred and then take the appropriate action. Also see [U] 16.1.4 Error handling in do-files.

The return codes are numerically grouped, which is a feature that you may find useful when you are writing programs. The groups are

<table>

</tbody>
</table>

Summary

1. You pressed Break. This is not considered an error.

2. connection timed out -- see help r(2) for troubleshooting
   An Internet connection has timed out. This can happen when the initial attempt to make a connection over the Internet has not succeeded within a certain time limit. You can change the time limit that Stata uses under this condition by typing `set timeout1 #seconds`. Or, the initial connection was successful, but a subsequent attempt to send or receive data over the Internet has timed out. You can also change this time limit by typing `set timeout2 #seconds`. See [R] netio.

3. no dataset in use
   You attempted to perform a command requiring data and have no data in memory.

4. no; data in memory would be lost
   You attempted to perform a command that would substantively alter or destroy the data, and the data have not been saved, at least since the data were last changed. If you wish to continue anyway, add the `clear` option to the end of the command. Otherwise, save the data first.

5. not sorted
   master data not sorted
   using data not sorted
   The observations of the data are not in the order required. To solve the problem, use `sort` to sort the data then reissue the command; see [D] sort.

   In the second and third cases, both the dataset in memory and the dataset on disk must be sorted by the variables specified in the varlist of `merge` before they can be merged. `merge` automatically sorts the datasets for you, unless you specify the `sorted` option. You specified `sorted`, but your dataset is not sorted on the variables in varlist. Do not specify `sorted`.

6. Return code from confirm existence when string does not exist.

7. ‘________’ found where _______ expected
   You are using a program that is using the confirm command to verify that what you typed makes sense. The messages indicate what you typed and what the program expected to find instead of what you typed.

8. assertion is false
   no action taken
   Return code and message from assert when the assertion is false: see [D] assert.
   Or, you were using mvencode and requested that Stata change ‘.’ to # in the specified varlist, but # already existed in the varlist, so Stata refused; see [D] mvencode.
18. you must start with an empty dataset
   The command (for example, infile) requires that no data be in memory—you must drop _all first. You are
   probably using infile to append additional data to the data in memory. Instead, save the data in memory, drop
   _all, infile the new data, and then append the previously saved data; see [D] append.

100. varlist required
    = exp required
    using required
    by() option required
   Certain commands require a varlist or another element of the language. The message specifies the required item
   that was missing from the command you gave. See the command’s syntax diagram. For example, merge requires
   using to be specified; perhaps you meant to type append. Or, ranksum requires a by() option; see [R] ranksum.

101. varlist not allowed
    weights not allowed
    in range not allowed
    if not allowed
    = exp not allowed
    using not allowed
   Certain commands do not allow an if qualifier or other elements of the language. The message specifies which
   item in the command is not allowed. See the command’s syntax diagram. For example, append does not allow a
   varlist; perhaps you meant to type merge.

102. too few variables specified
   The command requires more variables than you specified. For instance, stack requires at least two variables. See
   the syntax diagram for the command.

103. too many variables specified
   The command does not allow as many variables as you specified. For example, tabulate takes only one or two
   variables. See the syntax diagram for the command.

104. nothing to input
   You gave the input command with no varlist. Stata will input onto the end of the dataset, but there is no existing
   dataset here. You must specify the variable names on the input command.

106. variable ________ is ________ in master but ________ in using data
   You have attempted to append two datasets, but there is a string or numeric mismatch for one of the variables. The
   first blank is filled in with a variable name, and the second and third blanks are filled in with a storage type (byte, int, long, float, double, str#, or strL). You could specify append’s force option to ignore the mismatch.
   If the str# type is in the master data, the using variable would then be treated as if it contained ".", If the str# type is in the using data, the using variable would then be treated as if it contained numeric missing value.
   key variable ________ is strL in using data
   You have attempted to merge two datasets, but one of the key variables is a strL. The blank is filled in with the
   variable name. The key variables—the variables on which observations are matched—can be str#, but they
   cannot be strLs.

107. not possible with numeric variable
   You have requested something that is logically impossible with a numeric variable, such as encoding it. Perhaps
   you meant another variable or typed encode when you meant decode.

108. not possible with string variable
   You have requested something that is logically impossible with a string variable, such as decoding it. Perhaps you
   meant another variable or typed decode when you meant encode.

109. type mismatch
   In an expression, you attempted to combine a string and numeric subexpression in a logically impossible way. For
   instance, you attempted to subtract a string from a number or you attempted to take the substring of a number.

110. ________ already defined
    A variable or a value label has already been defined, and you attempted to redefine it. This occurs most often
    with generate. If you really intend to replace the values, use replace. If you intend to replace a value label,
    specify the replace option with the label define command. If you are attempting to alter an existing label,
    specify the add or modify option with the label define command.
error — Display generic error message and exit 205

111. _______ not found
no variables defined
The variable does not exist. You may have mistyped the variable’s name.

variables out of order
You specified a varlist containing varname1-varname2, yet varname1 occurs after varname2. Reverse the order of the variables if you did not make some other typographical error. Remember, varname1-varname2 is taken by Stata to mean varname1, varname2, and all the variables in dataset order in between. Type describe to see the order of the variables in your dataset.

_______ not found in using data
You specified a varlist with merge, but the variables on which you wish to merge are not found in the using dataset, so the merge is not possible.

_______ ambiguous abbreviation
You typed an ambiguous abbreviation for a variable in your data. The abbreviation could refer to more than one variable. Use a nonambiguous abbreviation, or if you intend all the variables implied by the ambiguous abbreviation, append a ‘*’ to the end of the abbreviation.

119. statement out of context
This is the generic form of this message; more likely, you will see messages such as “may not streset after ...”. You have attempted to do something that, in this context, is not allowed or does not make sense.

120. invalid \%fmt
You specified an invalid \%fmt; see [U] 12.5 Formats: Controlling how data are displayed.

Return codes 121–127 are errors that might occur when you specify a numlist. For details about numlist, see [U] 11.1.8 numlist.

121. invalid numlist
122. invalid numlist has too few elements
123. invalid numlist has too many elements
124. invalid numlist has elements out of order
125. invalid numlist has elements outside of allowed range
126. invalid numlist has noninteger elements
127. invalid numlist has missing values

130. expression too long
too many SUMs
In the first case, you specified an expression that is too long for Stata to process—the expression contains more than 249 pairs of nested parentheses or more than 800 dyadic operators. Break the expression into smaller parts. In the second case, the expression contains more than 5 sum() functions. This expression, too, will have to be broken into smaller parts.

131. not possible with test
You requested a test of a hypothesis that is nonlinear in the variables. test tests only linear hypotheses. Use testnl.

132. too many ‘(’ or ‘[
too many ‘)’ or ‘]’
You specified an expression with unbalanced parentheses or brackets.

133. unknown function ________()
You specified a function that is unknown to Stata; see Stata Functions Reference Manual. Or you may have meant to subscript a variable and accidentally used parentheses rather than square brackets; see [U] 13.7 Explicit subscripting.

134. too many values
1) You attempted to encode a string variable that takes on more than 65,536 unique values. 2) You attempted to tabulate a variable or pair of variables that take on too many values. If you specified two variables, try interchanging them. 3) You issued a graph command using the by option. The by-variable takes on too many different values to construct a readable chart.
135. **not possible with weighted data**
   You attempted to predict something other than the prediction or residual, but the underlying model was weighted. Stata cannot calculate the statistic you requested using weighted data.

140. **repeated categorical variable in term**
   At least one of the terms in your `anova` model or `test` statement has a repeated categorical variable, such as `reg#div#reg`. Either you forgot to specify that the variable is continuous or the second occurrence of the variable is unnecessary.

141. **repeated term**
   In the list of terms in your `anova` model or `test` statement is a duplicate of another term, although perhaps ordered differently. For instance, `X#A#X` and `A#X#X`. Remove the repeated term.

145. **term contains more than 8 variables**
   One of the terms in your `anova` model `test` statement contains more than eight variables. Stata cannot fit such models.

146. **too many variables or values (matsize too small)**
   You can increase matsize using the `set matsize` command; see help `matsize`. Your `anova` model resulted in a specification containing more than `matsize - 2` explanatory variables; see [R] `matsize`.

147. **term not in model**
   Your `test` command refers to a term that was not contained in your `anova` model.

148. **too few categories**
   You attempted to run a command that required specifying the number of groups, and the number specified was too small. For instance, you attempted to run the `brier` command and specified `group(#)` where `#` is less than 2.

149. **too many categories**
   You attempted to fit an `mprobit` or `slogit` model with a dependent variable that takes on more than 30 categories.

151. **non r-class program may not set r()**
   Perhaps you specified `return local` in your program but forgot to declare the program `rclass` in the `program` `define` statement.

152. **non e-class program may not set e()**
   Perhaps you specified `estimates local` in your program but forgot to declare the program `eclass` in the `program` `define` statement.

153. **non s-class program may not set s()**
   Perhaps you specified `sreturn local` in your program but forgot to declare the program `sclass` in the `program` `define` statement.

161. **ado-file has commands outside of program define ... end**
   All commands in ado-files must be part of Stata programs. That is, all commands must be between a `program define` that begins a program definition and an `end` that concludes a program definition. The command you typed automatically loaded an ado-file that violates this rule.

162. **ado-file does not define command**
   `xyz.ado` is supposed to define `xyz` and, perhaps, subroutines for use by `xyz`, in which case file `xyz.ado` did not define anything named `xyz`.

170. **unable to chdir**
   (Unix and Mac.) `cd` was unable to change to the directory you typed because it does not exist, it is protected, or it is not a directory.

175. **factor level out of range**
   You specified an invalid value for the level of a factor variable.

180. **invalid attempt to modify label**
   You are attempting to modify the contents of an existing value label by using the `label define` command. If you mean to completely replace the existing label, specify the `replace` option with the `label define` command. If you wish to modify the existing label, be sure to specify either the `add` option or the `modify` option on the `label define` command. `add` lets you add new entries but not change existing ones, and `modify` lets you do both. You will get this error if you specify `add` and then attempt to modify an existing entry. Then edit the command and substitute `modify` for the `add` option.

181. **may not label strings**
   You attempted to assign a value label to a string variable, which makes no sense.
182. _______ not labeled
   The indicated variable has no value label, yet your request requires a labeled variable. You may, for instance, be attempting to decode a numeric variable.

184. options _______ and _______ may not be combined
   For instance, you issued the regress command and tried to specify both the beta and the vce(cluster clustvar) options.

190. request may not be combined with by
   Certain commands may not be combined with by, and you constructed such a combination. See the syntax diagram for the command.
   in may not be combined with by
   in may never be combined with by. Use if instead; see [U] 11.5 by varlist: construct.

191. request may not be combined with by() option
   Certain commands may not be combined with the by() option, and you constructed such a combination. See the syntax diagram for the command.
   in may not be combined with by
   in may never be combined with by. Use if instead; see [U] 11.5 by varlist: construct.

196. could not restore sort order because variables were dropped
   You ran an ado-file program that has an error, and the program dropped the temporary marker variables that allow the sort order to be restored.

197. invalid syntax
   This error is produced by syntax and other parsing commands when there is a syntax error in the use of the command itself rather than in what is being parsed.

198. invalid syntax
   option _______ incorrectly specified
   option _______ not allowed
   _______ invalid
   range invalid
   _______ invalid obs no
   invalid filename
   _______ invalid varname
   _______ invalid name
   multiple by’s not allowed
   _______ found where number expected
   on or off required
   All items in this list indicate invalid syntax. These errors are often, but not always, due to typographical errors. Stata attempts to provide you with as much information as it can. Review the syntax diagram for the designated command.
   In giving the message “invalid syntax”, Stata is not helpful. Errors in specifying expressions often result in this message.

199. unrecognized command
   Stata failed to recognize the command, program, or ado-file name, probably because of a typographical or abbreviation error.

301. last estimates not found
   You typed an estimation command, such as regress, without arguments or attempted to perform a test or typed predict, but there were no previous estimation results.

302. last test not found
   You have requested the redisplay of a previous test, yet you have not run a test previously.

303. equation not found
   You referred to a coefficient or stored result corresponding to an equation or outcome that cannot be found. For instance, you estimated an mlogit model and the outcome variable took on the values 1, 3, and 4. You referred to [2]_b[var] when perhaps you meant [#2]_b[var] or [3]_b[var].

304. ml model not found
   You have used mleval, mlsum, or mlmatsum without having first used the other ml commands to define the model.

305. ml model not found
   Same as 304.
310. not possible because object(s) in use
   This can occur with *mata describe* and *mata drop* and indicates that the objects referred to cannot be described or eliminated because an earlier iteration of Mata is currently using them.

321. requested action not valid after most recent estimation command
   This message can be produced by *predict* or *test* and indicates that the requested action cannot be performed.

322. something that should be true of your estimation results is not
   This error is used by prefix commands and postestimation commands to indicate that the estimation command returned an unexpected result and that the prefix or postestimation command does not know how to proceed.

399. may not drop constant
   You issued a *logistic* or *logit* command and the constant was dropped. Your model may be underidentified; try removing one or more of the independent variables.

401. may not use noninteger frequency weights
   You specified an *fweight* frequency weight with noninteger weights, telling Stata that your weights are to be treated as replication counts. Stata encountered a weight that was not an integer, so your request made no sense. You probably meant to specify *aweight* analytic weights; see [U] 11.1.6 weight.

402. negative weights encountered
    negative weights not allowed
   You specified a variable that contains negative values as the weighting variable, so your request made no sense. Perhaps you meant to specify another variable.

404. not possible with pweighted data
   You requested a statistic that Stata cannot calculate with *pweight* data, either because of a shortcoming in Stata or because the statistics of the problem have not been worked out. For example, perhaps you requested the standard error of the Kaplan–Meier survival curve, and you had previously specified *pweight* when you *stset* your data (a case where no one has worked out the statistics).

406. not possible with analytic weights
   You specified a command that does not allow analytic weights. See the syntax diagram for the command to see which types of weights are allowed.

407. weights must be the same for all observations in a group
    weights not constant for same observation across repeated variables
   For some commands, weights must be the same for all observations in a group for statistical or computational reasons. For the *anova* command with the repeated() option, weights must be constant for an observation across the repeated variables.

409. no variance
   You were using *lnskew0* or *bcskew0*, for instance, but the exp that you specified has no variance.

411. nonpositive values encountered
    time variable has negative values
   For instance, you have used *graph* with the xlog or ylog options, requesting log scales, and yet some of the data or the labeling you specified is negative or zero.
   Or perhaps you were using *ltable* and specified a time variable that has negative values.

412. redundant or inconsistent constraints
   For instance, you are estimating a constrained model with *mlogit*. Among the constraints specified is at least one that is redundant or inconsistent. A redundant constraint might constrain a coefficient to be zero that some other constraint also constrains to be zero. An inconsistent constraint might constrain a coefficient to be 1 that some other constraint constrains to be zero. List the constraints, find the offender, and then reissue the *mlogit* command omitting it.

416. missing values encountered
   You specified a variable with missing values in a place where Stata does not allow missing values.

420. groups found, 2 required
   You used a command (such as *ttest*), and the grouping variable you specified does not take on two unique values.

421. could not determine between-subject error term; use bse() option
   You specified the repeated() option to *anova*, but Stata could not automatically determine certain terms that are needed in the calculation; see [R] *anova*. 
422. could not determine between-subject basic unit; use bseunit() option
You specified the \texttt{repeated()} option to \texttt{anova}, but Stata could not automatically determine certain terms that are needed in the calculation; see [R] \texttt{anova}.

430. convergence not achieved
You have estimated a maximum likelihood model, and Stata’s maximization procedure failed to converge to a solution; see [R] \texttt{maximize}. Check if the model is identified.

450. \texttt{variable} is not a 0/1 variable
number of successes invalid
\texttt{p} invalid
\texttt{variable} takes on \texttt{number} values, not 2
You have used a command, such as \texttt{bitest}, that requires the variable take on only the values 0, 1, or missing, but the variable you specified does not meet that restriction. (You can also get this message from, for example, \texttt{bitesti}, when you specify a number of successes greater than the number of observations or a probability not between 0 and 1.)

451. invalid values for \texttt{time} variable
For instance, you specified \texttt{mytime} as a \texttt{time} variable, and \texttt{mytime} contains noninteger values.

452. invalid values for \texttt{factor} variable
You specified a variable that does not meet the factor-variable restrictions. Factor variables are assumed to take on only nonnegative integer values.

459. something that should be true of your data is not
data have changed since estimation
This is the generic form of this message; more likely, you will see messages such as “y must be between 0 and 1” or “x not positive”. You have attempted to do something that, given your data, does not make sense.

460. \texttt{fpc} must be \textless{}= 0
There is a problem with your \texttt{fpc} variable; see [SVY] \texttt{svyset}.

461. \texttt{fpc} for all observations within a \texttt{stratum} must be the same
There is a problem with your \texttt{fpc} variable; see [SVY] \texttt{svyset}.

462. \texttt{fpc} must be \textless{}= 1 if a rate, or \textgreater{}= no. sampled PSUs per stratum if PSU totals
There is a problem with your \texttt{fpc} variable; see [SVY] \texttt{svyset}.

463. sum of weights equals zero
sum of weights for subpopulation equals zero
When weights sum to zero, the requested statistic cannot be computed.

464. poststratum weights must be constant within poststrata
You have \texttt{svyset} your data and specified the \texttt{poststrata()} and \texttt{postweight()} options. The variable containing poststratum population sizes must be constant within each poststratum to be valid.

465. poststratum weights must be \textgreater{}= 0
You have \texttt{svyset} your data and specified the \texttt{postweight()} option. Poststratum population sizes cannot be negative.

466. standardization weights must be constant within standard strata
You are using the \texttt{mean}, \texttt{proportion}, or \texttt{ratio} command, and you specified the \texttt{stdweight()} option. The weight variable for standardization must be constant within each standard stratum.

467. standardization weights must be \textgreater{}= 0
You are using the \texttt{mean}, \texttt{proportion}, or \texttt{ratio} command, and you specified the \texttt{stdweight()} option. The standardization weights cannot be negative.

471. \texttt{esample()} invalid
This concerns \texttt{ereturn post}. The \texttt{varname} variable specified by the \texttt{esample(varname)} option must contain exclusively 0 and 1 values (never, for instance, 2 or missing). \texttt{varname} contains invalid values.

480. starting values invalid or some RHS variables have missing values
You were using \texttt{nl} and specified starting values that were infeasible, or you have missing values for some of your independent variables.

481. equation/system not identified
cannot calculate derivatives
You were using \texttt{reg3}, for instance, and the system that you have specified is not identified.
You specified an \texttt{nl fcn} for which derivatives cannot be calculated.
482. nonpositive value(s) among _______, cannot log transform
You specified an lnlsq option in ml that attempts to take the log of a nonpositive value.

491. could not find feasible values
You are using ml and it could not find starting values for which the likelihood function could be evaluated. You could try using ml search with the repeat() option to randomly try more values, or you could use ml init to specify valid starting values.

498. various messages
The statistical problem described in the message has occurred. The code 498 is not helpful, but the message is supposed to be. Return code 498 is reserved for messages that are unique to a particular situation.

499. various messages
The statistical problem described in the message has occurred. The code 499 is not helpful, but the message is supposed to be. Return code 499 is reserved for messages that are unique to a particular situation.

501. matrix operation not found
You have issued an unknown matrix subcommand or used matrix define with a function or operator that is unknown to Stata.

503. conformability error
You have issued a matrix command attempting to combine two matrices that are not conformable, for example, multiplying a 3×2 matrix by a 3×3 matrix. You will also get this message if you attempt an operation that requires a square matrix and the matrix is not square.

504. matrix has missing values
This return code is now infrequently used because, beginning with version 8, Stata now permits missing values in matrices.

505. matrix not symmetric
You have issued a matrix command that can be performed only on a symmetric matrix, and your matrix is not symmetric. While fixing their code, programmers are requested to admire our choice of the “symmetric” number 505—it is symmetric about the zero—for this error.

506. matrix not positive definite
You have issued a matrix command that can be performed only on a positive-definite matrix, and your matrix is not positive definite.

507. name conflict
You have issued a matrix post command, and the variance–covariance matrix of the estimators does not have the same row and column names, or if it does, those names are not the same as for the coefficient vector.

508. matrix has zero values
  matrix has zero values on diagonal
  matrix has zero or negative values
  matrix has zero or negative values on diagonal
A matrix is being used or produced that has zero or negative values where it should not. For instance, you used the matrix sweep() function, but the matrix had zero values on the diagonal.

509. matrix operators that return matrices not allowed in this context
Expressions returning nonmatrices, such as those in generate and replace, may use matrix functions returning scalars, such as trace(A), but may not include subexpressions evaluating to matrices, such as trace(A+B), which requires evaluating the matrix expression A+B. (Such subexpressions are allowed in the context of expressions returning matrices, such as those in matrix.)

601. file ______ not found
The filename you specified cannot be found. Perhaps you mistyped the name, or it may be on another CD or directory. If you are a Mac user, perhaps you had an unintentional blank at the beginning or ending of your filename when it was created. In Finder, click on the file to blacken the name. If you see anything other than a thin, even space on each side of the name, rename the file to eliminate the leading and trailing space characters.

602. file ______ already exists
You attempted to write over a file that already exists. Stata will never let you do this accidentally. If you really intend to overwrite the previous file, reissue the last command, specifying the replace option.

603. file ______ could not be opened
The file, although found, could not be opened. Check to see if it is currently open in another application or, if it is a file on your network, it is being used by another person. If it is not in use, check to see if the file is in a directory where you are allowed to create files.
604. log file already open
   You attempted to open a log file when one is already open. Perhaps you forgot that you have the file open or forgot to close it.

606. no log file open
   You have attempted to close, turn on, or turn off logging when no log file was open. Perhaps you forgot to open the log file.

607. no cmdlog file open
   You have attempted to close, turn on, or turn off logging when no cmdlog file was open. Perhaps you forgot to open the cmdlog file.

608. file is read-only; cannot be modified or erased
   The operating system has the file marked as read-only, meaning that changes cannot be made.

609. file xp format
   The designated file is stored in an unsupported cross-product format.

610. file ______ not Stata format
   The designated file is not a Stata-format file. This occurs most often with use, append, and merge. You probably typed the wrong filename.

611. record too long
   You have attempted to process a record that exceeds 524,275 characters by using formatted infile (that is, infile with a dictionary). When reading formatted data, records may not exceed this maximum. If the records are not formatted, you can read these data by using the standard infile command (that is, without a dictionary). There is no maximum record length for unformatted data.

612. unexpected end of file
   You used infile with a dictionary, and the file containing the dictionary ended before the ‘}’ character. Perhaps you forgot to type the closing brace, or perhaps you are missing a hard return at the end of your file. You may also get this message if you issued the command #delimit ; in a do-file and then subsequently forgot to use ‘;’ before the ‘end’ statement.

613. file does not contain dictionary
   You used infile with a dictionary, yet the file you specified does not begin with the word ‘dictionary’. Perhaps you are attempting to infile data without using a dictionary and forgot to specify the varlist on the infile command. Or you forgot to include the word dictionary at the top of the dictionary file or typed DICTIONARY in uppercase.

614. dictionary invalid
   You used infile with a dictionary, and the file appears to contain a dictionary. Nevertheless, you have made some error in specifying the dictionary, and Stata does not understand your intentions. The contents of the dictionary are listed on the screen, and the last line is the line that gave rise to the problem.

616. wrong number of values in checksum file
   The checksum file being used to verify integrity of another file does not contain values in the expected checksum format.

621. already preserved
   You specified preserve, but you have already preserved the data.

622. nothing to restore
   You issued the restore command, but you have not previously specified preserve.

Return codes 630–696 are all messages that you might receive when executing any command with a file over the network.

631. host not found

632. web filename not supported in this context

633. may not write files over Internet

639. file transmission error (check sums do not match)

640. package file too long

641. package file invalid
651. may not seek past end of file
   may not seek in write-append file
   You may not seek past the end of a file; if your desire is to increase the file’s length, you must seek to the end and then write.

660. proxy host not found
   The host name specified as a proxy server cannot be mapped to an IP address. Type query to determine the host you have set.

662. proxy server refused request to send
   Stata was able to contact the proxy server, but the proxy server refused to send data back to Stata. The proxy host or port specified may be incorrect. Type query to determine your settings.

663. remote connection to proxy failed -- see help r(663) for troubleshooting
   Although you have set a proxy server, it is not responding to Stata. The likely problems are that you specified the wrong port, you specified the wrong host, or the proxy server is down. Type query to determine the host and port that you have set.

665. could not set socket nonblocking
667. wrong version winsock.dll
668. could not find a valid winsock.dll
669. invalid URL
670. invalid network port number
671. unknown network protocol
672. server refused to send file
673. authorization required by server
674. unexpected response from server
675. server reported server error
676. server refused request to send
677. remote connection failed -- see help r(663) for troubleshooting
   You requested that something be done over the web, but Stata could not contact the specified host. Perhaps the host is down; try again later.
   If all your web access results in this message, perhaps your network connection is via a proxy server. If it is, you must tell Stata. Contact your system administrator and ask for the name and port of the “http proxy server”. See http://www.stata.com/support/tech-support/contact/ for Stata contact information.

678. could not open local network socket
681. too many open files
682. could not connect to odbc dsn
   This typically occurs because of incorrect permissions, such as a bad User Name or Password. Use set debug on to display the actual error message generated by the ODBC driver.
683. could not fetch variable in odbc table
   This error usually occurs when a requested variable is not found in the current ODBC data table. Other scenarios can generate this error, however, so use set debug on to display the error message generated by the ODBC driver.
688. file is corrupt
691. I/O error
   A filesystem error occurred during input or output. This typically indicates a hardware or operating system failure, although it is possible that the disk was merely full and this state was misinterpreted as an I/O error.
692. file I/O error on read
693. file I/O error on write
694. could not rename file
   The file is in a directory that is marked by the operating system as read-only, and therefore files in that directory cannot be modified.
could not copy file
You tried to perform an update swap but Stata could not make a backup copy of the Stata executable, so the update was not performed.

insufficient disk space
You ran out of disk space while writing a file to disk. The file is now closed and is probably erased. Review your operating system documentation to determine how to proceed.

op. sys. refused to start new process

op. sys. refused to open pipe

system administrator will not allow you to change this setting

no room to add more variables
Stata just attempted to exceed the maximum number of variables allowed. If you are using Stata/SE or Stata/MP, you can reset this maximum number; see [D] memory. For Stata/IC, the maximum number is fixed at 2,048.

no room to add more observations
Stata just attempted to exceed the maximum number of observations allowed. This maximum number is 1,099,511,627,775 for Stata/MP and 2,147,483,647 for Stata/SE and Stata/IC.

no room to add more variables because of width
Width refers to the number of bytes required to store a single observation; it is the sum of the widths of the individual variables. You just attempted to exceed the maximum width. Try typing compress; see [D] compress.

no room to promote variable (e.g., change int to float) because of width
Width refers to the number of bytes required to store a single observation; it is the sum of the widths of the individual variables. You just attempted to exceed the maximum width. Try typing compress; see [D] compress.

maxvar too small
You have attempted to use an interaction with too many levels or attempted to fit a model with too many variables. You need to increase maxvar. Use set maxvar; see [D] memory.

If you are using factor variables and included an interaction that has numerous missing cells, either increase maxvar or set emptycells drop to reduce the required matrix size; see [R] set emptycells.

If you are using factor variables, you might have accidentally treated a continuous variable as a categorical, resulting in lots of categories. Use the c. operator on such variables.

matsize too small
You have attempted to create a matrix with too many rows or columns or attempted to fit a model with too many variables. You need to increase matsize. Use set matsize; see [R] matsize.

If you are using factor variables and included an interaction that has lots of missing cells, either increase matsize or set emptycells drop to reduce the required matrix size; see [R] set emptycells.

If you are using factor variables, you might have accidentally treated a continuous variable as a categorical, resulting in lots of categories. Use the c. operator on such variables.

op. sys. refuses to provide memory
The message above can vary. Stata was unable to allocate more memory, either because the operating system refused or because of Stata’s max_memory setting (see [D] memory). The message will provide the details.

value too small
You attempted to change the size of memory but specified values for memory, maximum observations, maximum width, or maximum variables that are too small. Stata wants to allocate a minimum of 300 K.

value too large
You attempted to change the size of memory but specified values for memory, maximum observations, maximum width, or maximum variables that are too large.

op. sys. refuses to provide sufficient memory
The message above can vary. You attempted to set matsize or set segmentsize, and the operating system was unable to provide sufficient memory. The message will provide the details.
914. op. sys. refused to allow Stata to open a temporary file

To honor your request for memory, Stata needed to open a temporary disk file, and the operating system said that it could not do so. This most often occurs under Unix, and then the text of the error message provided more information on how to repair the problem.

920. too many macros

You specified a line containing recursive macro substitutions. An example of single-level recursion is referring to "$this" when $this contains "$that" and $that contains "result". The result of evaluating "$this" is to produce "result". Double-level recursion would be when $this contains "$that" and $that contains "$what" and $what contains "result". Error 920 arises when the recursion level is greater than 20.

Error 920 also arises if macro substitution would result in text longer than the maximum number of characters allowed in a macro. See [R] limits.

950. insufficient memory

There is insufficient memory to fulfill the request. Type discard, press Return, and try the command again. If that fails, consider dropping value labels, variable labels, or macros.

1000. system limit exceeded – see manual

See [R] limits.

1001. too many values

You have attempted to create a table that has too many rows or columns. For a one-way table, the maximum number of rows is 12,000 for Stata/MP and Stata/SE and 3,000 for Stata/IC. For a two-way table, the maximum number of rows and columns is 1,200 by 80 for Stata/MP and Stata/SE and 300 by 20 for Stata/IC. Thus tabulate y x may not result in too many values even if tabulate x y does.

1002. too many by variables

The number of by variables exceeded 32,766 for Stata/MP or Stata/SE, or 2,048 for Stata/IC. You cannot exceed these maximums.

1003. too many options

The number of options specified exceeded 70. You cannot exceed this maximum.

1004. command too long

You attempted to issue a Stata command in a do-file, ado-file, or program, and the command exceeded 264,408 characters for Stata/IC. For Stata/MP and Stata/SE, the limit is $33*max_k_theory + 216$, which for the default setting of 5,000 is 165,216.

1400. numerical overflow

You have attempted something that, in the midst of the necessary calculations, has resulted in something too large for Stata to deal with accurately. Most commonly, this is an attempt to estimate a model (say, with regress) with too many effective observations. This effective number could be reached with far fewer observations if you were running a frequency-weighted model.

2000. no observations

You have requested some statistical calculation and there are no observations on which to perform it. Perhaps you specified if or in and inadvertently filtered all the data.

2001. insufficient observations

You have requested some statistical calculation, and although there are some observations, the number is not sufficient to carry out your request.

4000–4999. Class system errors; see [P] class for information on the class system.

9xxx. Various messages, all indicating an unexpected system failure. You should never see such a message. If one occurs, save your data, and exit Stata immediately. Please email tech-support@stata.com to report the problem.
error — Display generic error message and exit  215

Other messages

no observations
insufficient observations
You have requested something when there are either no observations or insufficient observations in memory to carry forth your request.

(_______ not found)
You referred to the indicated value name in an expression, and no such value label existed. A missing value was substituted.

(eof before end of obs)
infile was reading your data and encountered the end-of-file marker before it had completed reading the current observation. Missing values are filled in for the remaining variables. This message indicates that the dataset may contain more or fewer variables than you expected.

(_______ missing values generated)
The command created the indicated number of missing values. Missing values occur when a mathematical operation is performed on a missing value or when a mathematical operation is infeasible.

(note: file _______ not found)
You specified the replace option on a command, yet no such file was found. The file was saved anyway.

(note: variable ____ was _____, now _____ to accommodate using data’s values)
Occurs during append or merge when there is a type mismatch between the data in memory and the data on disk. The first blank is filled in with a variable name, and the second and third blanks with a storage type (byte, int, long, float, double, or str#, or strL). For instance, you might receive the message “variable myvar was str5, now strL to accommodate using data’s values”. This means that myvar is of type str5 in the master dataset and of type strL in the using dataset.

(label _______ already defined)
Occurs during append or merge. The using data has a label definition for one of its variables. A label with the same name exists in the master dataset. Thus you are warned that the label already exists, and the previous definition (the one from the master dataset) is retained.

(note: hascons false)
You specified the hascons option on regress, yet an examination of the data revealed that there is no effective constant in your varlist. Stata added a constant to your regression.

_____ real changes made
You used replace. This is the actual number of changes made to your data, not counting observations that already contained the replaced value.

____ was _____ now _____
Occurs during replace, append, or merge. The first blank is filled in with a variable name, and the second and third blanks are filled in with a numeric storage type (byte, int, long, float, or double). For instance, you might receive the message “myvar was byte now float”. Stata automatically promoted myvar to a float to prevent truncation.

[U] 16.1.4 Error handling in do-files
Programmers of estimation commands can customize how `estat` works after their commands. If you want to use only the standard `estat` subcommands, `ic`, `summarize`, and `vce`, you do not need to do anything; see [R] `estat`. Stata will automatically handle those cases.

### Remarks and examples

Remarks are presented under the following headings:

- **Standard subcommands**
- **Adding subcommands to `estat`**
- **Overriding standard behavior of a subcommand**

### Standard subcommands

For `estat` to work, your estimation command must be implemented as an e-class program, and it must store its name in `e(cmd)`. `estat vce` requires that the covariance matrix be stored in `e(V)`, and `estat summarize` requires that the estimation sample be marked by the function `e(sample)`. Both requirements can be met by using `ereturn post` with the `esample()` option in your program; see [P] `ereturn`.

Finally, `estat ic` requires that your program store the final log likelihood in `e(ll)` and the sample size in `e(N)`. If your program also stores the log likelihood of the null (constant only) model in `e(ll_0)`, it will appear in the output of `estat ic`, as well.

### Adding subcommands to `estat`

To add new features (subcommands) to `estat` for use after a particular estimation command, you write a handler, which is nothing more than an ado-file command. The standard is to name the new command `cmd_estat`, where `cmd` is the name of the corresponding estimation command. For instance, the handler that provides the special `estat` features after `regress` is named `regress_estat`, and the handler that provides the special features after `pca` is named `pca_estat`.

Next you must let `estat` know about your new handler, which you do by filling in `e(estat_cmd)` in the corresponding estimation command. For example, in the code that implements `pca` is the line

```
ereturn local estat_cmd "pca_estat"
```

Finally, you must write `cmd_estat`. The syntax of `estat` is

```
estat subcmd .
```

When the `estat` command is invoked, the first and only thing it does is call `‘e(estat_cmd)’` if `‘e(estat_cmd)’` exists. This way, your handler can even do something special in the standard cases, if that is necessary. We will get to that, but in the meantime, understand that the handler receives just what `estat` received, which is exactly what the user typed. The outline for a handler is
estat programming — Controlling estat after user-written commands 217

begin cmd_estat.ado

program cmd_estat, rclass
    version 15.0
    if "e(cmd)" != "cmd" {
        error 301
    }
    gettoken subcmd rest : 0, parse(" ,")
    if "subcmd"=="first_special_subcmd" {
        First_special_subcmd 'rest'
    }
    else if "subcmd"=="second_special_subcmd" {
        Second_special_subcmd 'rest'
    }
    else {
        estat_default '0'
    }
    return add
end

program First_special_subcmd, rclass
    syntax ...
    ...
end

program Second_special_subcmd, rclass
    syntax ...
    ...

end cmd_estat.ado

The ideas underlying the above outline are simple:

1. You check that e(cmd) matches cmd.
2. You isolate the subcmd that the user typed and then see if it is one of the special cases that you wish to handle.
3. If subcmd is a special case, you call the code you wrote to handle it.
4. If subcmd is not a special case, you let Stata’s estat_default handle it.

When you check for the special cases, those special cases can be new subcmds that you wish to add, or they can be standard subcmds whose default behavior you wish to override.

Example 1

Suppose that we have written the estimation command myreg and want the estat subcommands fit and sens to work after it, in addition to the standard subcommands. Moreover, we want to be able to abbreviate sens as se or sen. The following code fragment illustrates the structure of our myreg_estat handler program:
Say that we issue the command

```
estat sen, myoption("Circus peanuts")
```

The only way that the above differs from the standard outline is the complication we added to handle the abbreviation of `subcmd sens`. Rather than asking if 

```
"'subcmd'" == "sens"
```

we asked if

```
"'subcmd'" == substr("sens",1,max(2,'lsubcmd'))
```

where `lsubcmd` was previously filled in with `length("'subcmd'")`.

### Overriding standard behavior of a subcommand

Occasionally, you may want to override the behavior of a subcommand normally handled by `estat_default`. This is accomplished by providing a local handler. Consider, for example, `summarize` after `pca`. The standard way of invoking `estat summarize` is not appropriate here—`estat summarize` extracts the list of variables to be summarized from `e(b)`. This does not work after `pca`. Here the varlist has to be extracted from the column names of the correlation or covariance matrix `e(C)`. This varlist is transferred to `estat summarize` (or more directly to `estatsumm`) as the argument of the standard `estatsumm` program.

```
program Summarize
    syntax [, *] 
    tempname C 
    matrix 'C' = e(C) 
    estatsumm ':colnames 'C'', 'options'
end
```
You add the local handler by inserting an additional switch in `cmd_estat` to ensure that the `summarize` subcommand is not handled by the default handler `estat_default`. As a detail, we have to make sure that the minimal abbreviation is `summarize`.

```
begin pca_estat.ado

program pca_estat, rclass
    version 15.0
    gettoken subcmd rest : 0, parse("", ")
    local lsubcmd = length("subcmd")
    if "subcmd" == substr("summarize", 1, max(2, lsubcmd)) {
        Summarize 'rest'
    } else {
        estat_default '0'
    }
    return add
end

program Summarize
    syntax ...
    ...
end
```

```

[R] estat — Postestimation statistics
```
estimates hold, estimates unhold, estimates dir, estimates clear, and estimates drop provide a low-level mechanism for setting aside and later restoring up to 300 estimation results.

estimates hold moves, or copies if the copy option is specified, all information associated with the last estimation command into holdname. If holdname is a temporary name, it will automatically be deleted when you exit from the current program.

estimates unhold restores the information from the estimation command previously moved into holdname and eliminates holdname.

estimates dir lists the holdnames under which estimation results are currently held.

estimates clear eliminates all set aside results. Also, if the restore option is specified when the estimates are held, those estimates will be automatically restored when the program concludes. It is not necessary to perform an estimates unhold in that case.

estimates drop eliminates the estimation results stored under the specified holdnames.

estimates is a programmer’s command designed to be used within programs. estimates is a user’s command to manage multiple estimation results. estimates uses estimates to hold and unhold results, and it adds features such as model-selection indices and looping over results. Postestimation commands, such as suest and lrtest, assume that estimation results are stored using estimates rather than estimates.

Syntax

Move estimation results into holdname

estimates hold holdname [, copy restore nullok varname(newvar)]

Restore estimation results

estimates unhold holdname [, not]

List names holding estimation results

estimates dir

Eliminate estimation results

estimates clear

Eliminate specified estimation results

estimates drop { holdnames | _all }

where holdname is the name under which estimation results will be held.
Options

copy requests that all information associated with the last estimation command be copied into holdname. By default, it is moved, meaning that the estimation results temporarily disappear. The default action is faster and uses less memory.

restore requests that the information in holdname be automatically restored when the program ends, regardless of whether that occurred because the program exited normally, the user pressed Break, or there was an error.

nullok specifies that it is valid to store null results. After restoring a null result, no estimation results are active.

varname(newvar) specifies the variable name under which esample() will be held. If varname() is not specified, holdname is used. If the variable already exists in the data, an error message is shown. This variable is visible to users. If it is dropped, _estimates unhold will not be able to restore the estimation sample e(sample) and sets e(sample) to 1.

not specifies that the previous _estimates hold, restore request for automatic restoration be canceled. The previously held estimation results are discarded from memory without restoration, now or later.

Remarks and examples

_estimates hold and _estimates unhold are typically used in programs and ado-files, although they can be used interactively. After fitting, say, a regression by using regress, you can replay the regression by typing regress without arguments, and you can obtain predicted values with predict, and the like; see [U] 20 Estimation and postestimation commands. This is because Stata stored information associated with the regression in what we will call the “last estimation results”. The last estimation results include the coefficient vector and the variance–covariance matrix, as well as the other e() stored results.

When you type _estimates hold myreg, Stata moves the last estimation results to a holding area named myreg. After issuing this command, you can no longer replay the regression, calculate predicted values, etc. From Stata’s point of view, the estimates are gone. When you type _estimates unhold myreg, however, Stata moves the estimates back. You can once again type regress without arguments, calculate predicted values, and everything else just as if the last estimation results were never disturbed.

If you instead type _estimates hold myreg, copy, Stata copies, rather than moves, the results, meaning that you can still redisplay results. Obviously, you hold estimates because you want to fit some other model and then get these estimates back, so generally, holding by moving works as well as holding by copying. Sometimes, however, you may want to hold by copy so that you can modify the estimates in memory and still retrieve the original.
Example 1

You could run a regression, hold the results, run another regression, and then unhold the original results. One method you could use is

```
regress y x1 x2 x3               (fit first model)
_estimates hold model1
regress y x1 x2 x3 x4            (fit the second model)
_estimates hold model2
use newdata                      (use another dataset)
_estimates unhold model1         (get the first model)
predict yhat1                    (predict using first regression)
_estimates unhold model2         (get the second model)
predict yhat2                    (predict using second regression)
```

You are not limited to doing this with regression; you can do this with any estimation command.

Technical note

Warning: Holding estimation results can tie up considerable amounts of memory, depending on the kind of model and the number of variables in it. This is why there is a limit of 300 held estimation results.

```
estimates dir, _estimates drop, and _estimates clear are utilities associated with
_estimates hold and _estimates unhold. _estimates dir lists the names of held estimation results. _estimates drop drops held estimation results. _estimates clear is equivalent to
_estimates drop _all.
```

Technical note

Despite our interactive example, _estimates hold and _estimates unhold are typically used inside programs. For instance, linktest fits a model of the dependent variable, the prediction, and the prediction squared and shows the result. Yet when it is over, the user’s original model remains as the last estimation result just as if no intervening model had been estimated. linktest does this by holding the original model, performing its task, and then restoring the original model.

In addition to moving Stata’s last estimation result matrices, \textit{e(b)} and \textit{e(V)}, _estimates hold and _estimates unhold also move the other \textit{e()} results. When you hold the current estimates, \textit{e(b)}, \textit{e(V)}, \textit{e(cmd)}, \textit{e(depvar)}, and the other \textit{e()} results disappear. When you unhold them, they are restored.

To avoid naming conflicts, we recommend that estimates be held under a name created by \texttt{tempvar} or \texttt{tempname}; see \cite{P} macro. Thus the code fragment is

```
tempvar est
_estimates hold est
(code including new estimation)
_estimates unhold est
```

Estimates held under a temporary name will automatically be discarded when the program ends. You can also specify _estimates hold’s restore option when you hold the estimates, and then the held estimates will be restored when the program ends, too.

**Stored results**

_estimates hold removes the estimation results—e() items.
_estimates unhold restores the previously held e() results.
_estimates clear permanently removes all held e() results.
_estimates dir returns the names of the held estimation results in the local r(names), separated by single spaces.
_estimates dir also returns r(varnames), which has the corresponding variable names for esample().

Title

**estimation command — How to program an estimation command**

Description

Information on programming estimation commands is given in *The Stata Blog*. Below, we reproduce the blog *Programming an estimation command in Stata: A map to posted entries* (Drukker 2016a).

Remarks and examples

I have posted a series of entries about programming an estimation command in Stata. They are best read in order. The comprehensive list below allows you to read them from first to last at your own pace.

1. **Programming estimators in Stata: Why you should**
   
   To help you write Stata commands that people want to use, I illustrate how Stata syntax is predictable and give an overview of the estimation–postestimation structure that you will want to emulate in your programs.

2. **Programming an estimation command in Stata: Where to store your stuff**
   
   I discuss the difference between scripts and commands, and I introduce some essential programming concepts and constructions that I use to write the scripts and commands.

3. **Programming an estimation command in Stata: Global macros versus local macros**
   
   I discuss a pair of examples that illustrate the differences between global macros and local macros.

4. **Programming an estimation command in Stata: A first ado-command**
   
   I discuss the code for a simple estimation command to focus on the details of how to implement an estimation command. The command that I discuss estimates the mean by the sample average. I begin by reviewing the formulas and a do-file that implements them. I subsequently introduce ado-file programming and discuss two versions of the command. Along the way, I illustrate some of the postestimation features that work after the command.

5. **Programming an estimation command in Stata: Using Stata matrix commands and functions to compute OLS objects**
   
   I present the formulas for computing the ordinary least-squares (OLS) estimator, and I discuss some do-file implementations of them. I discuss the formulas and the computation of independence-based standard errors, robust standard errors, and cluster–robust standard errors. I introduce the Stata matrix commands and matrix functions that I use in ado-commands that I discuss in upcoming posts.

6. **Programming an estimation command in Stata: A first command for OLS**
   
   I show how to write a Stata estimation command that implements the OLS estimator by explaining the code.
7. Programming an estimation command in Stata: A better OLS command

I use the `syntax` command to improve the command that implements the OLS estimator that I discussed in Programming an estimation command in Stata: A first command for OLS. I show how to require that all variables be numeric variables and how to make the command accept time-series–operated variables.

8. Programming an estimation command in Stata: Allowing for sample restrictions and factor variables

I modify the OLS command discussed in Programming an estimation command in Stata: A better OLS command to allow for sample restrictions, to handle missing values, to allow for factor variables, and to deal with perfectly collinear variables.

9. Programming an estimation command in Stata: Allowing for options

I make three improvements to the command that implements the OLS estimator that I discussed in Programming an estimation command in Stata: Allowing for sample restrictions and factor variables. First, I allow the user to request a robust estimator of the variance–covariance of the estimator. Second, I allow the user to suppress the constant term. Third, I store the residual degrees of freedom in `e(df_r)` so that test will use the $t$ or $F$ distribution instead of the normal or chi-squared distribution to compute the $p$-value of Wald tests.

10. Programming an estimation command in Stata: Using a subroutine to parse a complex option

I make two improvements to the command that implements the OLS estimator that I discussed in Programming an estimation command in Stata: Allowing for options. First, I add an option for a cluster–robust estimator of the variance–covariance of the estimator (VCE). Second, I make the command accept the modern syntax for either a robust or a cluster–robust estimator of the VCE. In the process, I use subroutines in my ado-program to facilitate the parsing, and I discuss some advanced parsing tricks.

11. Programming an estimation command in Stata: Mata 101

I introduce Mata, the matrix programming language that is part of Stata.

12. Programming an estimation command in Stata: Mata functions

I show how to write a function in Mata, the matrix programming language that is part of Stata.

13. Programming an estimation command in Stata: A first ado-command using Mata

I discuss a sequence of ado-commands that use Mata to estimate the mean of a variable. The commands illustrate a general structure for Stata–Mata programs.

14. Programming an estimation command in Stata: Computing OLS objects in Mata

I present the formulas for computing the OLS estimator and show how to compute them in Mata. This post is a Mata version of Programming an estimation command in Stata: Using Stata matrix commands and functions to compute OLS objects. I discuss the formulas and the computation of independence-based standard errors, robust standard errors, and cluster–robust standard errors.

15. Programming an estimation command in Stata: An OLS command using Mata

I discuss a command that computes OLS results in Mata, paying special attention to the structure of Stata programs that use Mata work functions.
16. Programming an estimation command in Stata: Adding robust and cluster–robust VCEs to our Mata-based OLS command

I show how to use the undocumented command \_vce\_parse to parse the options for robust or cluster–robust estimators of the VCE. I then discuss myregress12.ado, which performs its computations in Mata and computes an independent and identically distributed based, a robust, or a cluster–robust estimator of the VCE.

17. Programming an estimation command in Stata: A review of nonlinear optimization using Mata

I review the theory behind nonlinear optimization and get some practice in Mata programming by implementing an optimizer in Mata. This post is designed to help you develop your Mata programming skills and to improve your understanding of how the Mata optimization suites optimize() and moptimize() work.

18. Programming an estimation command in Stata: Using optimize() to estimate Poisson parameters

I show how to use optimize() in Mata to maximize a Poisson log-likelihood function and to obtain estimators of the VCE based on independent and identically dependent observations or on robust methods.

19. Programming an estimation command in Stata: A poisson command using Mata

I discuss mypoisson1, which computes Poisson-regression results in Mata. The code in mypoisson1.ado is remarkably similar to the code in myregress11.ado, which computes OLS results in Mata, as I discussed in Programming an estimation command in Stata: An OLS command using Mata.

20. Programming an estimation command in Stata: Handling factor variables in optimize()

I discuss a method for handling factor variables when performing nonlinear optimization using optimize(). After illustrating the issue caused by factor variables, I present a method and apply it to an example using optimize().

21. Programming an estimation command in Stata: Handling factor variables in a poisson command using Mata

mypoisson2.ado handles factor variables and computes its Poisson-regression results in Mata. I discuss the code for mypoisson2.ado, which I obtained by adding the method for handling factor variables discussed in Programming an estimation command in Stata: Handling factor variables in optimize() to mypoisson1.ado, discussed in Programming an estimation command in Stata: A poisson command using Mata.

22. Programming an estimation command in Stata: Allowing for robust or cluster–robust standard errors in a poisson command using Mata

mypoisson3.ado adds options for a robust or a cluster–robust estimator of the VCE to mypoisson2.ado, which I discussed in Programming an estimation command in Stata: Handling factor variables in a poisson command using Mata. mypoisson3.ado parses the vce() option using the techniques I discussed in Programming an estimation command in Stata: Adding robust and cluster–robust VCEs to our Mata-based OLS command. I show how to use optimize() to compute the robust or cluster–robust VCE.

23. Programming an estimation command in Stata: Adding analytical derivatives to a poisson command using Mata

Using analytically computed derivatives can greatly reduce the time required to solve a nonlinear estimation problem. I show how to use analytically computed derivatives with optimize(), and I discuss mypoisson4.ado, which uses these analytically computed derivatives. Only a few lines of mypoisson4.ado differ from the code for mypoisson3.ado, which I discussed in
Programming an estimation command in Stata: Allowing for robust or cluster–robust standard errors in a poisson command using Mata.

24. Programming an estimation command in Stata: Making predict work

I make predict work after mypoisson5 by writing an ado-command that computes the predictions and by having mypoisson5 store the name of this new ado-command in e(predict).

25. Programming an estimation command in Stata: Certifying your command

Before you use or distribute your estimation command, you should verify that it produces correct results and write a do-file that certifies that it does so. I discuss the processes of verifying and certifying an estimation command, and I present some techniques for writing a do-file that certifies mypoisson5, which I discussed in previous posts.

26. Programming an estimation command in Stata: Nonlinear least-squares estimators

I want to write ado-commands to estimate the parameters of an exponential conditional mean model and probit conditional mean model by nonlinear least squares. Before I can write these commands, I need to show how to trick optimize() into performing the Gauss–Newton algorithm and apply this trick to these two problems.

27. Programming an estimation command in Stata: Consolidating your code

I write ado-commands that estimate the parameters of an exponential conditional mean model and a probit conditional mean model by nonlinear least squares, using the methods that I discussed in Programming an estimation command in Stata: Nonlinear least-squares estimators. These commands will either share lots of code or repeat lots of code, because they are so similar. It is almost always better to share code than to repeat code. Shared code only needs to be changed in one place to add a feature or to fix a problem; repeated code must be changed everywhere. I introduce Mata libraries to share Mata functions across ado-commands, and I introduce wrapper commands to share ado-code.

28. Programming an estimation command in Stata: Writing an estat postestimation command

estat commands display statistics after estimation. Many of these statistics are diagnostics or tests used to evaluate model specification. Some statistics are available after all estimation commands; others are command specific. I illustrate how estat commands work and then show how to write a command-specific estat command for the mypoisson command that I have been developing.

[U] 20 Estimation and postestimation commands
exit — Exit from a program or do-file

Description

exit, when typed from the keyboard, causes Stata to terminate processing and returns control to the operating system. If the dataset in memory has changed since the last save command, you must specify the clear option before Stata will let you leave. Use of the command in this way is discussed in [R] exit.

More generally, exit causes Stata to terminate the current process and returns control to the calling process. The return code is set to the value of the expression or to zero if no expression is specified. Thus exit can be used to exit a program or do-file and return control to Stata. With an option, exit can even be used to exit Stata from a program or do-file. Such use of exit is the subject of this entry.

Syntax

```
exit [ [ = ] exp ] [, clear STATA]
```

Options
clear permits you to exit, even if the current dataset has not been saved.

STATA exits Stata and returns control to the operating system, even when given from a do-file or program. The STATA option is implied when exit is issued from the keyboard.

Remarks and examples

exit can be used at the terminal, from do-files, or from programs. From the terminal, it allows you to leave Stata. Given from a do-file or program without the STATA option, it causes the do-file or program to terminate and return control to the calling process, which might be the keyboard or another do-file or program.

Caution should be used if exit is included to break execution within a loop. A more suitable command is continue or continue, break; see [P] continue. continue is used to explicitly break execution of the current loop iteration with execution resuming at the top of the loop unless the break option is specified, in which case execution resumes with the command following the looping command.

When using exit to force termination of a program or do-file, you may specify an expression following the exit, and the resulting value of that expression will be used to set the return code. Not specifying an expression is equivalent to specifying exit 0.
Example 1

Here is a useless program that will tell you whether a variable exists:

```
. program check
  1. capture confirm variable ‘1’
  2. if _rc!=0 {
  3.    display ”‘1’ not found”
  4.    exit
  5. }
  6. display ”The variable ‘1’ exists.”
  7. end
```

```
. check median_age
The variable median_age exists.
```

```
. check age
age not found
```

exit did not close Stata and cause a return to the operating system; it instead terminated the program.

Example 2

You type `exit` from the keyboard to leave Stata and return to the operating system. If the dataset in memory has changed since the last time it was saved, however, Stata will refuse. At that point, you can either `save` the data and then `exit` or type `exit, clear`:

```
. exit
no; data in memory would be lost
r(4);
```

```
. exit, clear
(Operating system prompts you for next command)
```

Technical note

You can also exit Stata and return to the operating system from a do-file or program by including the line `exit, STATA` in your do-file or program. To return to the operating system regardless of whether the dataset in memory has changed, you include the line `exit, STATA clear`.

[R] `exit` — Exit Stata
Description

file is a programmer’s command and should not be confused with import delimited (see [D] import delimited), infile (see [D] infile (free format) or [D] infile (fixed format)), and infix (see [D] infix (fixed format)), which are the usual ways that data are brought into Stata. file allows programmers to read and write both text and binary files, so file could be used to write a program to input data in some complicated situation, but that would be an arduous undertaking.

Files are referred to by a file handle. When you open a file, you specify the file handle that you want to use; for example, in

`. file open myfile using example.txt, write`

myfile is the file handle for the file named example.txt. From that point on, you refer to the file by its handle. Thus

`. file write myfile "this is a test" _n`

would write the line “this is a test” (without the quotes) followed by a new line into the file, and

`. file close myfile`

would then close the file. You may have multiple files open at the same time, and you may access them in any order.

For information on reading and writing sersets, see [P] serset.
Syntax

Open file

```
file open handle using filename , {read|write|read write}
   [[text|binary] [replace|append] all]
```

Read file

```
file read handle [specs]
```

Write to file

```
file write handle [specs]
```

Change current location in file

```
file seek handle {query|tof|eof|#}
```

Set byte order of binary file

```
file set handle byteorder {hilo|lohi|1|2}
```

Close file

```
file close {handle | _all}
```

List file type, status, and name of handle

```
file _query
```

where specs for text output is

- "string" or ‘"string"’,
- (exp) (parentheses are required)
- %fmt(exp) (see [D] format about %fmt)
- _skip(#) 
- _column(#) 
- _newline[#] 
- _char(#) (0 ≤ # ≤ 255) 
- _tab[#] 
- _page[#] 
- _dup(#)
specs for text input is `localmacroname`,
specs for binary output is

\[
\begin{align*}
%{8|4}z & \quad (exp) \\
%{4|2|1}b[s|u] & \quad (exp) \\
%\#s & \quad "text" \quad (1 \leq \# \leq \text{max\_macrolen}) \\
%\#s & \quad "text"' \\
%\#s & \quad (exp)
\end{align*}
\]

and specs for binary input is

\[
\begin{align*}
%{8|4}z & \quad \text{scalarname} \\
%{4|2|1}b[s|u] & \quad \text{scalarname} \\
%\#s & \quad \text{localmacroname} \quad (1 \leq \# \leq \text{max\_macrolen})
\end{align*}
\]

**Options**

read, write, or read write is required; they specify how the file is to be opened. If the file is opened read, you can later use `file read` but not `file write`; if the file is opened write, you can later use `file write` but not `file read`. If the file is opened read write, you can then use both.

read write is more flexible, but most programmers open files purely read or purely write because that is all that is necessary; it is safer and it is faster.

When a file is opened read, the file must already exist, or an error message will be issued. The file is positioned at the top (tof), so the first `file read` reads at the beginning of the file. Both local files and files over the net may be opened for read.

When a file is opened write and the replace or append option is not specified, the file must not exist, or an error message will be issued. The file is positioned at the top (tof), so the first `file write` writes at the beginning of the file. Net files may not be opened for write.

When a file is opened write and the replace option is also specified, it does not matter whether the file already exists; the existing file, if any, is erased beforehand.

When a file is opened write and the append option is also specified, it also does not matter whether the file already exists; the file will be reopened or created if necessary. The file will be positioned at the append point, meaning that if the file existed, the first `file write` will write at the first byte past the end of the previous file; if there was no previous file, `file write` begins writing at the first byte in the file. `file seek` may not be used with write append files.

When a file is opened read write, it also does not matter whether the file exists. If the file exists, it is reopened. If the file does not exist, a new file is created. Regardless, the file will be positioned at the top of the file. You can use `file seek` to seek to the end of the file or wherever else you desire. Net files may not be opened for read write.

Before opening a file, you can determine whether it exists by using `confirm file`; see [P] `confirm`. text and binary determine how the file is to be treated once it is opened. text is the default. With text, files are assumed to be composed of lines of characters, with each line ending in a line-end character. The character varies across operating systems, being line feed under Unix, carriage return under Mac, and carriage return/line feed under Windows. file understands all the ways that lines might end when reading and assumes that lines are to end in the usual way for the computer being used when writing.
The alternative to text is binary, meaning that the file is to be viewed merely as a stream of bytes. With binary, there is an issue of byte order; consider the number 1 written as a 2-byte integer. On some computers (called hilo), it is written as “00 01”, and on other computers (called lohi), it is written as “01 00” (with the least significant byte written first). There are similar issues for 4-byte integers, 4-byte floats, and 8-byte floats.

file assumes that the bytes are ordered in the way natural to the computer being used. file set can be used to vary this assumption. file set can be issued immediately after file open, or later, or repeatedly.

replace and append are allowed only when the file is opened for write (which does not include read write). They determine what is to be done if the file already exists. The default is to issue an error message and not open the file. See the description of the options read, write, and read write above for more details.

all is allowed when the file is opened for write or for read write. It specifies that, if the file needs to be created, the permissions on the file are to be set so that it is readable by everybody.

Text output specifications

"string" and ‘"string’ write string into the file, without the surrounding quotes.

(exp) evaluates the expression exp and writes the result into the file. If the result is numeric, it is written with a %10.0g format, but with leading and trailing spaces removed. If exp evaluates to a string, the resulting string is written, with no extra leading or trailing blanks.

%f/form exp evaluates expression exp and writes the result with the specified %/fmt. If exp evaluates to a string, %/fmt must be a string format, and, correspondingly, if exp evaluates to a real, a numeric format must be specified. Do not confuse Stata’s standard display formats with the binary formats %b and %z described elsewhere in this entry. file write here allows Stata’s display formats described in [D] format and allows the centering extensions (for example, %-20s) described in [P] display.

_SKIP(#) inserts # blanks into the file. If # ≤ 0, nothing is written; # ≤ 0 is not considered an error.

_COLUMN(#) writes enough blanks to skip forward to column # of the line; if # refers to a prior column, nothing is displayed. The first column of a line is numbered 1. Referring to a column less than 1 is not considered an error; nothing is displayed then.

_NEWLINE[(#)], which may be abbreviated _n[(#)], outputs one end-of-line character if # is not specified or outputs the specified number of end-of-line characters. The end-of-line character varies according to your operating system, being line feed under Unix, carriage return under Mac, and the two characters carriage return/line feed under Windows. If # ≤ 0, no end-of-line character is output.

_CHAR(#) outputs one ASCII character, being the one given by the ASCII code # specified. # must be between 0 and 255, inclusive.

_TAB[(#)outputs one tab character if # is not specified or outputs the specified number of tab characters. Coding _tab is equivalent to coding _char(9).

_PAGE[(#)] outputs one page feed character if # is not specified or outputs the specified number of page feed characters. Coding _page is equivalent to coding _char(12). The page feed character is often called Control-L.

_DUP(#) specified that the next directive is to be executed (duplicated) # times. # must be greater than or equal to 0. If # is equal to zero, the next element is not displayed.
Remarks and examples

Remarks are presented under the following headings:

- Use of file
- Use of file with tempfiles
- Writing text files
- Reading text files
- Use of seek when writing or reading text files
- Writing and reading binary files
- Writing binary files
- Reading binary files
- Use of seek when writing or reading binary files

Appendix A.1 Useful commands and functions for use with file
Appendix A.2 Actions of binary output formats with out-of-range values

Use of file

file provides low-level access to file I/O. You open the file, use file read or file write repeatedly to read or write the file, and then close the file with file close:

```
file open ...
...
file read or file write ...
...
file read or file write ...
...
file close ...
```

Do not forget to close the file. Open files tie up system resources. Also, for files opened for writing, the contents of the file probably will not be fully written until you close the file.

Typing file close _all will close all open files, and the clear all command (see [D] clear) closes all files as well. These commands, however, should not be included in programs that you write; they are included to allow the user to reset Stata when programmers have been sloppy.

If you use file handles obtained from tempname (see [P] macro), the file will be automatically closed when the ado-file terminates:

```
tempname myfile
file open `myfile' using ...
```

This is the only case when not closing the file is appropriate. Use of temporary names for file handles offers considerable advantages because programs can be stopped because of errors or because the user presses Break.
Use of file with tempfiles

In the rare event that you `file open` a tempfile, you must obtain the handle from `tempname`; see [P] `macro`. Temporary files are automatically deleted when the ado- or do-file ends. If the file is erased before it is closed, significant problems are possible. Using a `tempname` will guarantee that the file is properly closed beforehand:

```
    tempname myfile
tempfile tfile
    file open 'myfile' using "'tfile'" ...
```

Writing text files

This is easy to do:

```
    file open handle using filename, write text
    file write handle ...
    ...
    file close handle
```

The syntax of `file write` is similar to that of `display`; see [P] `display`. The significant difference is that expressions must be bound in parentheses. In `display`, you can code

```
    display 2+2
```

but using `file write`, you must code

```
    file write handle (2+2)
```

The other important difference between `file write` and `display` is that `display` assumes you want the end-of-line character output at the end of each `display` (and `display` provides `_continue` for use when you do not want this), but `file write` assumes you want an end-of-line character only when you specify it. Thus rather than coding "`file write handle (2+2)`", you probably want to code

```
    file write handle (2+2) _n
```

Because Stata outputs end-of-line characters only where you specify, coding

```
    file write handle "first part is " (2+2) _n
```

has the same effect as coding

```
    file write handle "first part is 
    file write handle (2+2) _n
```
or even

```plaintext
file write handle "first part is "
file write handle (2+2)
file write handle \_n
```

There is no limit to the line length that `file write` can write because, as far as `file write` is concerned, \_n is just another character. The \_col(#) directive, however, will lose count if you write lines of more than 2,147,483,646 characters (\_col(#) skips forward to the specified column). In general, we recommend that you do not write lines longer than 165,199 characters because reading lines longer than that is more difficult using `file read`.

We say that \_n is just another character, but we should say character or characters. \_n outputs the appropriate end-of-line character for your operating system, meaning the two-character carriage return followed by line feed under Windows, the one-character carriage return under Mac, and the one-character line feed under Unix.

### Reading text files

The commands for reading text files are similar to those for writing them:

```plaintext
file open handle using filename, read text
file read handle localmacroname
...
file close handle
```

The `file read` command has one syntax:

```plaintext
file read handle localmacroname
```

One line is read from the file, and it is put in `localmacroname`. For instance, to read a line from the file `myfile` and put it in the local macro `line`, you code

```plaintext
file read myfile line
```

Thereafter in your code, you can refer to `line` to obtain the contents of the line just read. The following program will do a reasonable job of displaying the contents of the file, putting line numbers in front of the lines:

```plaintext
program ltype
  version 15.0
  local 0 "using 0",
  syntax using/
  tempfile fh,
  local linenum = 0
  file open 'fh' using "using", read
  file read 'fh' line
  while r(eof)==0 {
    local linenum = 'linenum' + 1
    display %4.0f 'linenum' _asis " 'macval(line)'",
    file read 'fh' line
  }
  file close 'fh'
end
```
In the program above, we used `tempname` to obtain a temporary name for the file handle. Doing that, we ensure that the file will be closed, even if the user presses `Break` while our program is displaying lines, and so never executes `file close ‘fh’`. In fact, our `file close ‘fh’` line is unnecessary.

We also used `r(eof)` to determine when the file ends. `file read` sets `r(eof)` to contain 0 before end of file and 1 once end of file is encountered; see `Stored results` below.

We included `_asis` in the `display` in case the file contained braces or SMCL commands. These would be interpreted, and we wanted to suppress that interpretation so that `ltype` would display lines exactly as written in the file; see `[P] smcl`. We also used the `macval()` macro function to obtain what was in `‘line’` without recursively expanding the contents of line.

### Use of seek when writing or reading text files

You may use `file seek` when reading or writing text files, although, in fact, it is seldom used, except with `read write` files, and even then, it is seldom used with text files.

See `Use of seek when writing or reading binary files` below for a description of `file seek`—`seek` works the same way with both text and binary files—and then bear the following in mind:

- The `#` in `“file seek handle #”` refers to byte position, not line number. `“file seek handle 5”` means to seek to the fifth byte of the file, not the fifth line.

- When calculating byte offsets by hand, remember that the end-of-line character is 1 byte under Mac and Unix but is 2 bytes under Windows.

- Rewriting a line of an text file works as expected only if the new and old lines are of the same length.

### Writing and reading binary files

Consider whether you wish to read this section. There are many potential pitfalls associated with binary files, and, at least in theory, a poorly written binary-I/O program can cause Stata to crash.

Binary files are made up of binary elements, of which Stata can understand the following:

<table>
<thead>
<tr>
<th>Element</th>
<th>Corresponding format</th>
</tr>
</thead>
<tbody>
<tr>
<td>single- and multiple-character strings</td>
<td>%1s and %#s</td>
</tr>
<tr>
<td>signed and unsigned 1-byte binary integers</td>
<td>%1b, %1bs, and %1bu</td>
</tr>
<tr>
<td>signed and unsigned 2-byte binary integers</td>
<td>%2b, %2bs, and %2bu</td>
</tr>
<tr>
<td>signed and unsigned 4-byte binary integers</td>
<td>%4b, %4bs, and %4bu</td>
</tr>
<tr>
<td>4-byte IEEE floating-point numbers</td>
<td>%4z</td>
</tr>
<tr>
<td>8-byte IEEE floating-point numbers</td>
<td>%8z</td>
</tr>
</tbody>
</table>

The differences between all of these types are only of interpretation. For instance, the decimal number 72, stored as a 1-byte binary integer, also represents the character H. If a file contained the 1-byte integer 72 and you were to read the byte by using the format `%1s`, you would get back the character “H”, and if a file contained the character “H” and you were to read the byte by using the format `%1bu`, you would get back the number 72; 72 and H are indistinguishable in that they represent the same bit pattern. Whether that bit pattern represents 72 or H depends on the format you use, meaning the interpretation you give to the field.
Similar equivalence relations hold between the other elements. A binary file is nothing more than a sequence of unsigned 1-byte integers, where those integers are sometimes given different interpretations or are grouped and given an interpretation. In fact, all you need is the format `%1bu` to read or write anything. The other formats, however, make programming more convenient.

<table>
<thead>
<tr>
<th>Format</th>
<th>Length</th>
<th>Type</th>
<th>Minimum</th>
<th>Maximum</th>
<th>Missing values?</th>
</tr>
</thead>
<tbody>
<tr>
<td>%1bu</td>
<td>1</td>
<td>unsigned byte</td>
<td>0</td>
<td>255</td>
<td>no</td>
</tr>
<tr>
<td>%1bs</td>
<td>1</td>
<td>signed byte</td>
<td>−127</td>
<td>127</td>
<td>no</td>
</tr>
<tr>
<td>%1b</td>
<td>1</td>
<td>Stata byte</td>
<td>−127</td>
<td>100</td>
<td>yes</td>
</tr>
<tr>
<td>%2bu</td>
<td>2</td>
<td>unsigned short int</td>
<td>0</td>
<td>65,535</td>
<td>no</td>
</tr>
<tr>
<td>%2bs</td>
<td>2</td>
<td>signed short int</td>
<td>−32,767</td>
<td>32,767</td>
<td>no</td>
</tr>
<tr>
<td>%2b</td>
<td>2</td>
<td>Stata int</td>
<td>−32,767</td>
<td>32,740</td>
<td>yes</td>
</tr>
<tr>
<td>%4bu</td>
<td>4</td>
<td>unsigned int</td>
<td>0</td>
<td>4,294,967,295</td>
<td>no</td>
</tr>
<tr>
<td>%4bs</td>
<td>4</td>
<td>signed int</td>
<td>−2,147,483,647</td>
<td>2,147,483,647</td>
<td>no</td>
</tr>
<tr>
<td>%4b</td>
<td>4</td>
<td>Stata long</td>
<td>−2,147,483,647</td>
<td>2,147,483,620</td>
<td>yes</td>
</tr>
<tr>
<td>%4z</td>
<td>4</td>
<td>float</td>
<td>$-10^{38}$</td>
<td>$10^{38}$</td>
<td>yes</td>
</tr>
<tr>
<td>%8z</td>
<td>8</td>
<td>double</td>
<td>$-10^{307}$</td>
<td>$10^{307}$</td>
<td>yes</td>
</tr>
</tbody>
</table>

When you write a binary file, you must decide on the format that you will use for every element that you will write. When you read a binary file, you must know ahead of time the format that was used for each element.

**Writing binary files**

As with text files, you open the file, write repeatedly, and then close the file:

```
    file open handle using filename, write binary
    file write handle ...
    file write handle ...
    file close handle
```

The `file write` command may include the following elements:

- `%{8|4}z` (exp)
- `%{4|2|1}b{s|u}` (exp)
- `%#s "text"` (1 ≤ # ≤ max_macrolen)
- `%#s "text"` (exp)
- `%#s (exp)`

For instance, to write “test file” followed by 2, 2 + 2, and 3 × 2 represented in its various forms, you could code

```
    . file write handle %9s "test file" %8z (2) %4b (2+2) %1bu (3*2)
```

or

```
    . file write handle %9s "test file"
    . file write handle %8z (2) %4b (2+2) %1bu (3*2)
```
or even

```
file handle %9s "test file"
file write handle %8z (2)
file write handle %4b (2+2) %1bu (3*2)
```

eetc.

You write strings with the '%#s' format and numbers with the '%b' or '%z' formats. Concerning strings, the '#' in '%#s' should be greater than or equal to the length of the string to be written in bytes. If '#' is too small, only that many characters of the string will be written. Thus

```
file write handle %4s "test file"
```

would write “test” into the file and leave the file positioned at the fifth byte. There is nothing wrong with coding that (the “test” can be read back easily enough), but this is probably not what you intended to write.

Also concerning strings, you can output string literals—just enclose the string in quotes—or you can output the results of string expressions. Expressions, as for using `file write` to output text files, must be enclosed in parentheses:

```
file write handle %4s (substr(a,2,6))
```

The following program will output a user-specified matrix to a user-specified file; the syntax of the command being implemented is

```
mymatout1 matname using filename [, replace]
```

and the code is

```bash
program mymatout1
    version 15.0
    gettoken mname 0 : 0
    syntax using/ [, replace]
llocal r = rowsof('mname')
llocal c = colsof('mname')
tempname hdl
    file open 'hdl' using "'using'", 'replace' write binary
    file write 'hdl' %2b ('r') %2b ('c')
        forvalues i=1(1)'r' {
            forvalues j=1(1)'c' {
                file write 'hdl' %8z ('mname'['i','j'])
            }
        }
    file close 'hdl'
end
```

A significant problem with `mymatout1` is that, if we wrote a matrix on our Unix computer (an Intel-based computer) and copied the file to a SPARC-based computer, we would discover that we could not read the file. Intel computers write multiple-byte numbers with the least-significant byte first; SPARC-based computers write the most-significant byte first. Who knows what your computer does? Thus even though there is general agreement across computers on how numbers and characters are written, this byte-ordering difference is enough to stop binary files.

`file` can handle this problem for you, but you have to insert a little code. The recommended procedure is this: before writing any numbers in the file, write a field saying which byte order this computer uses (see `byteorder()` in [FN] Programming functions). Later, when we write the command to read the file, it will read the ordering that we recorded. We will then tell `file` which
byte ordering the file is using, and file itself will reorder the bytes if that is necessary. There are other ways that we could handle this—such as always writing in a known byte order—but the recommended procedure is better because it is, on average, faster. Most files are read on the same computer that wrote them, and thus the computer wastes no time rearranging bytes then.

The improved version of mymatout1 is

```stata
program mymatout2
    version 15.0
    gettoken mname 0 : 0
    syntax using/[ , replace]
    local r = rowsof('mname')
    local c = colsof('mname')
    tempname hdl
    file open 'hdl' using '', 'replace' write binary
        /* new */
        file write 'hdl' %1b (byteorder())
        file write 'hdl' %2b ('r') %2b ('c')
        forvalues i=1(1)'r' {
            forvalues j=1(1)'c' {
                file write 'hdl' %8z ('mname'[i,j])
            }
        }
    file close 'hdl'
end
```

`byteorder()` returns 1 if the machine is hilo and 2 if lohi, but all that matters is that it is small enough to fit in a byte. The important thing is that we write this number using `%1b`, about which there is no byte-ordering disagreement. What we do with this number we will deal with later.

The second significant problem with our program is that it does not write a signature. Binary files are difficult to tell apart: they all look like binary junk. It is important that we include some sort of marker at the top saying who wrote this file and in what format it was written. That is called a signature. The signature that we will use is

```
mymatout 1.0.0
```

We will write that 14-byte-long string first thing in the file so that later, when we write `mymatin`, we can read the string and verify that it contains what we expect. Signature lines should always contain a generic identity (`mymatout` here) along with a version number, which we can change if we modify the output program to change the output format. This way, the wrong input program cannot be used with a more up-to-date file format.
Our improved program is

```
program mymatout3
  version 15.0
  gettoken mname 0 : 0
  syntax using/ [, replace]
  local r = rowsof('mname')
  local c = colsof('mname')
  tempname hdl
  file open 'hdl' using "\"using\"", 'replace' write binary
  /* new */
  file write 'hdl' %14s "mymatout 1.0.0"
  file write 'hdl' %1b (byteorder())
  file write 'hdl' %2b ('r') %2b ('c')
  forvalues i=1(1)'r' {
    forvalues j=1(1)'c' {
      file write 'hdl' %8z ('mname'['i','j'])
    }
  }
  file close 'hdl'
end
```

This program works well. After we wrote the corresponding input routine (see Reading binary files below), however, we noticed that our restored matrices lacked their original row and column names, which led to a final round of changes:

```
program mymatout4
  version 15.0
  gettoken mname 0 : 0
  syntax using/ [, replace]
  local r = rowsof('mname')
  local c = colsof('mname')
  tempname hdl
  file open 'hdl' using "\"using\"", 'replace' write binary
  /* changed */
  file write 'hdl' %14s "mymatout 1.0.1"
  file write 'hdl' %1b (byteorder())
  file write 'hdl' %2b ('r') %2b ('c')
  /* new */
  local names : rownames 'mname'
  local len : length local names
  /* new */
  file write 'hdl' %4b ('len') %'len's 'names'
  /* new */
  local names : colnames 'mname'
  local len : length local names
  /* new */
  file write 'hdl' %4b ('len') %'len's 'names'
  forvalues i=1(1)'r' {
    forvalues j=1(1)'c' {
      file write 'hdl' %8z ('mname'['i','j'])
    }
  }
  file close 'hdl'
end
```

In this version, we added the lines necessary to write the row and column names into the file. We write the row names by coding

```
local names : rownames 'mname'
local len : length local names
file write 'hdl' %4b ('len') %'len's 'names'
```

and we similarly write the column names. The interesting thing here is that we need to write a string into our binary file for which the length of the string varies. One solution would be

```
file write 'hdl' %165199s 'mname'
```
but that would be inefficient because, in general, the names are much shorter than 165,199 bytes. The solution is to obtain the length of the string to be written and then write the length into the file. In the above code, macro ‘\texttt{len}’ contains the length, we write ‘\texttt{len}’ as a 4-byte integer, and then we write the string using a ‘\%\texttt{len}’s format. Consider what happens when ‘\texttt{len}’ is, say, 50. We write 50 into the file, and then we write the string using a ‘\%50s’ format. Later, when we read back the file, we can reverse this process, reading the length and then using the appropriate format.

We also changed the signature from “mymatout 1.0.0” to “mymatout 1.0.1” because the file format changed. Making that change ensures that an old read program does not attempt to read a more modern format (and so produce incorrect results).

\begin{itemize}
\item \textbf{Technical note}
\end{itemize}

You may write strings using ‘\%#s’ formats that are narrower than, equal to, or wider than the length of the string being written. When the format is too narrow, only that many characters of the string are written. When the format and string are of the same width, the entire string is written. When the format is wider than the string, the entire string is written, and then the excess positions in the file are filled with binary zeros.

Binary zeros are special in strings because binary denotes the end of the string. Thus when you read back the string, even if it was written in a field that was too wide, it will appear exactly as it appeared originally.

\begin{itemize}
\item \textbf{Reading binary files}
\end{itemize}

You read binary files just as you wrote them,

\begin{verbatim}
    file open handle using filename, read binary
    file read handle ...
    ...
    file close handle
\end{verbatim}

When reading them, you must be careful to specify the same formats as you did when you wrote the file.

The program that will read the matrices written by \texttt{mymatout1}, presented below, has the syntax

\begin{verbatim}
    mymatin1 matname filename
\end{verbatim}
and the code is

```plaintext
program mymatin1
  version 15.0
  gettoken mname 0 : 0
  syntax using/
  tempname hdl
  file open 'hdl' using "'using'"', read binary
  tempname val
  file read 'hdl' %2b 'val'
  local r = 'val'
  file read 'hdl' %2b 'val'
  local c = 'val'
  matrix 'mname' = J('r', 'c', 0)
  forvalues i=1(1)'r' {
    forvalues j=1(1)'c' {
      file read 'hdl' %8z 'val'
      matrix 'mname'['i','j'] = 'val'
    }
  }
  file close 'hdl'
end
```

When `file read` reads numeric values, they are always stored into scalars (see `[P] scalar`), and you specify the name of the scalar directly after the binary numeric format. Here we are using the scalar named `val`, where `val` is a name that we obtained from `tempname`. We could just as well have used a fixed name, say, `myscalar`, so the first `file read` would read

```
file read 'hdl' %2b myscalar
```

and we would similarly substitute `myscalar` everywhere `val` appears, but that would make our program less elegant. If the user had previously stored a value under the name `myscalar`, our values would replace it.

In the second version of `mymatout`, we included the byte order. The correspondingly improved version of `mymatin` is

```plaintext
program mymatin2
  version 15.0
  gettoken mname 0 : 0
  syntax using/
  tempname hdl
  file open 'hdl' using "'using'"', read binary
  tempname val
  /* new */ file read 'hdl' %1b 'val'
  /* new */ local border = 'val'
  /* new */ file set 'hdl' byteorder 'border'
  file read 'hdl' %2b 'val'
  local r = 'val'
  file read 'hdl' %2b 'val'
  local c = 'val'
  matrix 'mname' = J('r', 'c', 0)
  forvalues i=1(1)'r' {
    forvalues j=1(1)'c' {
      file read 'hdl' %8z 'val'
      matrix 'mname'['i','j'] = 'val'
    }
  }
  file close 'hdl'
end
```
We simply read back the value we recorded and then `file set` it. We cannot directly `file set` `handle` byteorder `‘val’` because `‘val’` is a scalar, and the syntax for `file set` byteorder is

```
file set handle byteorder {hilo|lohi|1|2}
```

That is, `file set` is willing to see a number (1 and hilo mean the same thing, as do 2 and lohi), but that number must be a literal (the character 1 or 2), so we had to copy `‘val’` into a macro before we could use it. Once we set the byte order, however, we could from then on depend on `file` to reorder the bytes for us should that be necessary.

In the third version of `mymatout`, we added a signature. In the modification below, we read the signature by using a `%14s` format. Strings are copied into local macros, and we must specify the name of the local macro following the format:

```
program mymatin3
    version 15.0
    gettoken mname 0 : 0
    syntax using/
    tempname hd1
    file open ‘hdl’ using ‘"using"’, read binary
    /* new */ file read ‘hdl’ %14s signature
    /* new */ if ”signature” != ”mymatout 1.0.0” {
        /* new */ disp as err ”file not mymatout 1.0.0”
        /* new */ exit 610
        /* new */ }
    /* new */
    tempname val
    file read ‘hdl’ %1b ‘val’
    local border = ‘val’
    file set ‘hdl’ byteorder ‘border’
    file read ‘hdl’ %2b ‘val’
    local r = ‘val’
    file read ‘hdl’ %2b ‘val’
    local c = ‘val’
    matrix ‘mname’ = J(r, c, 0)
    forvalues i=1(1)r {
        forvalues j=1(1)c {
            file read ‘hdl’ %8z ‘val’
            matrix ‘mname’[i,’j’] = ‘val’
        }
    }
    file close ‘hdl’
end
```

In the fourth and final version, we wrote the row and column names. We wrote the names by first preceding them with a 4-byte integer recording their width:
program mymatin4
    version 15.0
    gettoken mname 0 : 0
    syntax using/
    tempname hdl
    file open 'hdl' using "'using'\"', read binary
    file read 'hdl' %14s signature
    /* changed */ if "signature" != "mymatout 1.0.1" {
        /* changed */ disp as err "file not mymatout 1.0.1"
        exit 610
    }
    tempname val
    file read 'hdl' %1b 'val'
    local border = 'val'
    file set 'hdl' byteorder 'border'
    file read 'hdl' %2b 'val'
    local r = 'val'
    file read 'hdl' %2b 'val'
    local c = 'val'
    matrix 'mname' = J('r', 'c', 0)
    /* new */ file read 'hdl' %4b 'val'
    /* new */ local len = 'val'
    /* new */ file read 'hdl' %4b's names
    /* new */ matrix rownames 'mname' = 'names'
    /* new */ file read 'hdl' %4b 'val'
    /* new */ local len = 'val'
    /* new */ file read 'hdl' %4b's names
    /* new */ matrix colnames 'mname' = 'names'
    forvalues i=1(1)'r' {
        forvalues j=1(1)'c' {
            file read 'hdl' %8z 'val'
            matrix 'mname'['i','j'] = 'val'
        }
    }
    file close 'hdl'
end

Use of seek when writing or reading binary files

Nearly all I/O programs are written without using file seek. file seek changes your location in the file. Ordinarily, you start at the beginning of the file and proceed sequentially through the bytes. file seek lets you back up or skip ahead.

file seek handle query actually does not change your location in the file; it merely returns in scalar r(loc) the current position, with the first byte in the file being numbered 0, the second 1, and so on. In fact, all the file seek commands return r(loc), but file seek query is unique because that is all it does.

file seek handle tof moves to the beginning (top) of the file. This is useful with read files when you want to read the file again, but you can seek to tof even with write files and, of course, with read write files. (Concerning read files: you can seek to top, or any point, before or after the end-of-file condition is raised.)

file seek handle eof moves to the end of the file. This is useful only with write files (or read write files) but may be used with read files, too.
file seek handle # moves to the specified position. # is measured in bytes from the beginning of the file and is in the same units as reported in r(loc). ‘file seek handle 0’ is equivalent to ‘file seek handle tof’.

Technical note

When a file is opened write append, you may not use file seek. If you need to seek in the file, open the file read write instead.

Appendix A.1 Useful commands and functions for use with file

• When opening a file read write or write append, file’s actions differ depending upon whether the file already exists. confirm file (see [P] confirm) can tell you whether a file exists; use it before opening the file.

• To obtain the length of strings when writing binary files, use the macro extended function length:

        local length : length local mystr
        file write handle %'length’s “'mystr’”;

See Macro extended functions for parsing in [P] macro for details.

• To write portable binary files, we recommend writing in natural byte order and recording the byte order in the file. Then the file can be read by reading the byte order and setting it:

Writing:

        file write handle %1b (byteorder())

Reading:

        tempname mysca
        file read handle %1b ‘mysca’
        local b_order = ‘mysca’
        file set handle byteorder ‘b_order’

The byteorder() function returns 1 or 2, depending on whether the computer being used records data in hilo or lohi format. See [FN] Programming functions.

Appendix A.2 Actions of binary output formats with out-of-range values

Say that you write the number 2,137 with a %1b format. What value will you later get back when you read the field with a %1b format? Here the answer is ., Stata’s missing value, because the %1b format is a variation of %1bs that supports Stata’s missing value. If you wrote 2,137 with %1bs, it would read back as 127; if you wrote it with %1bu, it would read back as 255.

In general, in the Stata variation, missing values are supported, and numbers outside the range are written as missing. In the remaining formats, the minimum or maximum is written as
In the above table, if you write a missing value, take that as writing a value larger than the maximum allowed for the type.

If you write a noninteger value with an integer format, the result will be truncated to an integer. For example, writing 124.75 with a `%2b` format is the same as writing 124.

**Stored results**

`file read` stores the following in `r()`:

Scalars

- `r(eof)`
  - 1 on end of file; 0 otherwise

Macros

- `r(status)`: (if `text file`)
  - `win`: line read; line ended in cr-lf
  - `mac`: line read; line ended in cr
  - `unix`: line read; line ended in lf
  - `split`: line read; line was too long and so split
  - `none`: line read; line was not terminated
  - `eof`: line not read because of end of file

`r(status) = split` indicates that `c(macrolen) − 1(33maxvar+199)` for Stata/MP and Stata/SE, 165,199 for Stata/IC characters of the line were returned and that the next `file read` will pick up where the last read left off.

`r(status) = none` indicates that the entire line was returned, that no line-end character was found, and that the next `file read` will return `r(status) = eof`.

If `r(status) = eof` (`.r(eof) = 1`), then the local macro into which the line was read contains "". The local macro containing "", however, does not imply end of file because the line might simply have been empty.
file seek stores the following in r():
Scalars
r(loc) current position of the file

file query stores the following in r():
Scalars
r(N) number of open files

Description

Stata’s .dta datasets record data in a way generalized to work across computers that do not agree on how data are recorded. Thus the same dataset may be used, without translation, on different computers (Windows, Unix, and Mac computers). Given a computer, datasets are divided into two categories: native-format and foreign-format datasets. Stata uses the following two rules:

R1. On any computer, Stata knows how to write only native-format datasets.

R2. On all computers, Stata can read foreign-format as well as native-format datasets.

Rules R1 and R2 ensure that Stata users need not be concerned with dataset formats.

Stata is also continually being updated, and these updates sometimes require that changes be made to how Stata records .dta datasets. Stata can read older formats, but whenever it writes a dataset, it writes in the modern format.

Remarks and examples

For up-to-date documentation on the Stata .dta file format, type help dta. The system help file contains all the details a programmer will need. To obtain a copy of the help file in PostScript format, which you can then print, type

```
    . which dta.sthlp
    . translate help_file dta.ps, translator(smcl2ps)
```

The first command will show you where the help file is, and then you can type that name in the translate command. Even easier is

```
    . findfile dta.sthlp
    . translate "r(fn)" dta.ps, translator(smcl2ps)
```

Either way, you can then print the new file dta.ps from your current directory.

[U] 1.2.2 Example datasets
**findfile — Find file in path**

**Description**

`findfile` looks for a file along a specified path and, if the file is found, displays the fully qualified name and returns the name in `r(fn)`. If the file is not found, the file-not-found error, `r(601)`, is issued.

Unless told otherwise, `findfile` looks along the ado-path, the same path that Stata uses for searching for ado-files, help files, etc.

In programming contexts, `findfile` is usually preceded by `quietly`; see [P] quietly.

**Syntax**

```
findfile filename [, path(path) nodescend all]
```

where `filename` and `path` may optionally be enclosed in quotes, and the default is to look over the ado-path if option `path()` is not specified.

**Options**

`path(path)` specifies the path over which `findfile` is to search. Not specifying this option is equivalent to specifying `path(“c(adopath)”)`.

If specified, `path` should be a list of directory (folder) names separated by semicolons; for example,

```
path(“.;-/bin;-/data/my data;”)  
path(“.;\bin;\data\my data;”) 
```

The individual directory names may be enclosed in quotes, but if any are, remember to enclose the entire path argument in compound quotes.

Also any of the directory names may be specified as `STATA`, `BASE`, `SITE`, `PLUS`, `PERSONAL`, or `OLDPLACE`, which are indirect references to directories recorded by `sysdir` (see [P] sysdir):

```
path(BASE;SITE;PERSONAL;PLUS)  
path(\bin;\site;\personal;\plus)  
path(“\bin;\site\data\my data;PERSONAL;PLUS”)  
path(“.;c(adopath);”) 
```

`nodescend` specifies that `findfile` not follow Stata’s normal practice of searching in letter subdirectories of directories in the path, as well as in the directories themselves. `nodescend` is rarely specified, and, if it is specified, `path()` would usually be specified, too.
all specifies that all files along the path with the specified name are to be found and then listed
and stored in r(fn). When all is not specified, the default is to stop the search when the first
instance of the specified name is found.

When all is specified, the fully qualified names of the files found are returned in r(fn), listed
one after the other, and each enclosed in quotes. Thus when all is specified, if you later need
to quote the returned list, you must use compound double quotes. Also remember that findfile
issues a file-not-found error if no files are found. If you wish to suppress that and want r(fn)
returned containing nothing, precede findfile with capture; see [P] capture. Thus the typical
usage of findfile, all is

    . capture findfile filename, all
    . local filelist "'r(fn)'"

Remarks and examples

findfile is not a utility to search everywhere for a file that you have lost. findfile is for use
in those rare ado-files that use prerecorded datasets and for which you wish to place the datasets
along the ado-path, along with the ado-file itself.

For instance, Stata’s icd9 command performs a mapping, and that mapping is in fact stored
in a dataset containing original values and mapped values. Thus along with icd9.ado is dataset
icd9_cod.dta, and that dataset is stored along the ado-path, too. Users of icd9 know nothing
about the dataset. In icd9.ado, the icd9_cod.dta is merged with the data in memory. The code
fragment that does that reads

    . quietly findfile icd9_cod.dta
    . merge ... using "'r(fn)'"

It would not have been possible to code simply

    . merge ... using icd9_cod.dta

because icd9_cod.dta is not in the current directory.

Stored results

findfile stores the following in r():

    Macros
      r(fn) (all not specified) name of the file found; name not enclosed in quotes
      (all specified) names of the files found, listed one after the other, each enclosed in quotes

Also see

[P] sysdir — Query and set system directories
[P] unabcmd — Unabbreviate command name
[D] sysuse — Use shipped dataset
[R] which — Display location and version for an ado-file
foreach — Loop over items

Description

foreach repeatedly sets local macro \textit{name} to each element of the list and executes the commands enclosed in braces. The loop is executed zero or more times; it is executed zero times if the list is null or empty. Also see \texttt{forvalues}, which is the fastest way to loop over consecutive values, such as looping over numbers from 1 to \textit{k}.

\texttt{foreach \textit{name} in \textit{list} \{\ldots\}} allows a general list. Elements are separated from each other by one or more blanks.

\texttt{foreach \textit{name} of local \textit{list} \{\ldots\}} and \texttt{foreach \textit{name} of global \textit{list} \{\ldots\}} obtain the list from the indicated place. This method of using \texttt{foreach} produces the fastest executing code.

\texttt{foreach \textit{name} of varlist \textit{list} \{\ldots\}}, \texttt{foreach \textit{name} of newlist \textit{list} \{\ldots\}}, and \texttt{foreach \textit{name} of numlist \textit{list} \{\ldots\}} are much like \texttt{foreach \textit{name} in \textit{list} \{\ldots\}}, except that the \textit{list} is given the appropriate interpretation. For instance,

\begin{verbatim}
foreach x in mpg weight-turn {
    
    }
\end{verbatim}

has two elements, \textit{mpg} and \textit{weight-turn}, so the loop will be executed twice.

\begin{verbatim}
foreach x of varlist mpg weight-turn {
    
    }
\end{verbatim}

has four elements, \textit{mpg}, \textit{weight}, \textit{length}, and \textit{turn}, because \textit{list} was given the interpretation of a varlist.

\texttt{foreach \textit{name} of varlist \textit{list} \{\ldots\}} gives \textit{list} the interpretation of a varlist. The \textit{list} is expanded according to standard variable abbreviation rules, and the existence of the variables is confirmed.

\texttt{foreach \textit{name} of newlist \textit{list} \{\ldots\}} indicates that the \textit{list} is to be interpreted as new variable names; see \texttt{[U] 11.4.2 Lists of new variables}. A check is performed to see that the named variables could be created, but they are not automatically created.

\texttt{foreach \textit{name} of numlist \textit{list} \{\ldots\}} indicates a number list and allows standard number-list notation; see \texttt{[U] 11.1.8 numlist}.
Syntax

```plaintext
foreach lname \{ in | of listtype \} list \{
    commands referring to ‘lname’
\}
```

Allowed are

```plaintext
foreach lname in any_list \{

foreach lname of local lmacname \{

foreach lname of global gmacname \{

foreach lname of varlist varlist \{

foreach lname of newlist newvarlist \{

foreach lname of numlist numlist \{
```

Braces must be specified with `foreach`, and

1. the open brace must appear on the same line as `foreach`;
2. nothing may follow the open brace except, of course, comments; the first command to be executed must appear on a new line;
3. the close brace must appear on a line by itself.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- foreach ... of local and foreach ... of global
- foreach ... of varlist
- foreach ... of newlist
- foreach ... of numlist
- Use of foreach with continue
- The unprocessed list elements

Introduction

`foreach` has many forms, but it is just one command, and what it means is

```plaintext
foreach value of a list of things, set x equal to each and \{
    execute these instructions once per value
    and in the loop we can refer to ‘x’ to refer to the value
\}
```
and this is coded

```stata
foreach x ... {
    ... 'x' ...
}
```

We use the name `x` for illustration; you may use whatever name you like. The list itself can come from a variety of places and can be given a variety of interpretations, but `foreach x in` is easiest to understand:

```stata
foreach x in a b mpg 2 3 2.2 {
    ... 'x' ...
}
```

The list is `a`, `b`, `mpg`, `2`, `3`, and `2.2`, and appears right in the command. In some programming instances, you might know the list ahead of time, but often what you know is that you want to do the loop for each value of the list contained in a macro, for instance, `'varlist'`. Then you could code

```stata
foreach x in 'varlist' {
    ... 'x' ...
}
```

but your code will execute more quickly if you code

```stata
foreach x of local varlist {
    ... 'x' ...
}
```

Both work, but the second is quicker to execute. In the first, Stata has to expand the macro and substitute it into the command line, whereupon `foreach` must then pull back the elements one at a time and store them. In the second, all of that is already done, and `foreach` can just grab the local macro `varlist`.

The two forms we have just shown,

```stata
foreach x in ... {
    ... 'x' ...
}
```

and

```stata
foreach x of local ... {
    ... 'x' ...
}
```

are the two ways `foreach` is most commonly used. The other forms are for special occasions.

In the event that you have something that you want to be given the interpretation of a varlist, newvarlist, or numlist before it is interpreted as a list, you can code

```stata
foreach x of varlist mpg weight-turn g* {
    ... 'x' ...
}
```

or

```stata
foreach x of newlist id values1-values9 {
    ... 'x' ...
}
```
foreach — Loop over items

or

    foreach x of numlist 1/3 5 6/10 {
        ... `x' ...
    }

Just as with `foreach x in ...', you put the list right on the command line, and, if you have the list in a macro, you can put `macroname' on the command line.

If you have the list in a macro, you have no alternative but to code `macroname'; there is no special `foreach x of local macroname' variant for varlist, newvarlist, and numlist because, in those cases, `foreach x of local macroname' itself is probably sufficient. If you have the list in a macro, then how did it get there? Well, it probably was something that the user typed and that your program has already parsed. Then the list has already been expanded, and treating the list as a general list is adequate; it need not be given the special interpretation again, at least as far as `foreach' is concerned.

Example 1: Using `foreach', interactively

`foreach' is generally used in programs, but it may be used interactively, and for illustration we will use it that way. Three files are appended to the dataset in memory. The dataset currently in memory and each of the three files has only one string observation.

    . list 
       x
       1. data in memory
    . foreach file in this.dta that.dta theother.dta {
        2. append using `file'
        3. }
    . list 
       x
       1. data in memory
       2. data from this.dta
       3. data from that.dta
       4. data from theother.dta

Quotes may be used to allow elements with blanks.

    . foreach name in "Annette Fett" "Ashley Poole" "Marsha Martinez" {
        2. display length("name") " characters long -- 'name'
        3. }

12 characters long -- Annette Fett
12 characters long -- Ashley Poole
15 characters long -- Marsha Martinez

foreach ... of local and foreach ... of global

`foreach lname of local lmacname' obtains the blank-separated list (which may contain quotes) from local macro `lmacname'. For example,

    foreach file of local flist {
        ...
    }
produces the same results as typing

```
foreach file in 'flist' {
    ...
}
```

except that `foreach file of local flist` is faster, uses less memory, and allows the list to be modified in the body of the loop.

If the contents of `flist` are modified in the body of `foreach file in 'flist'`, `foreach` will not notice, and the original list will be used. The contents of `flist` may, however, be modified in `foreach file of local flist`, but only to add new elements onto the end.

`foreach lname of global gmacname` is the same as `foreach lname in $gmacname`, with the same three caveats as to speed, memory use, and modification in the loop body.

### Example 2: Looping over the elements of local and global macros

```
local grains "rice wheat flax"
foreach x of local grains {
    display "x"
}
rice
wheat
flax

global money "Dollar Lira Pound"
foreach y of global money {
    display "y"
}
Dollar
Lira
Pound
```

`foreach ... of varlist` 

`foreach lname of varlist varlist` allows specifying an existing variable list.
**Example 3: Looping over existing variables**

```
. foreach var of varlist pri-rep t* {
2.     quietly summarize 'var'
3.     summarize 'var' if 'var' > r(mean)
4. }
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>22</td>
<td>9814.364</td>
<td>3022.929</td>
<td>6229</td>
<td>15906</td>
</tr>
<tr>
<td>mpg</td>
<td>31</td>
<td>26.67742</td>
<td>4.628802</td>
<td>22</td>
<td>41</td>
</tr>
<tr>
<td>rep78</td>
<td>29</td>
<td>4.37931</td>
<td>.493804</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>trunk</td>
<td>40</td>
<td>17.1</td>
<td>2.351214</td>
<td>14</td>
<td>23</td>
</tr>
<tr>
<td>turn</td>
<td>41</td>
<td>43.07317</td>
<td>2.412367</td>
<td>40</td>
<td>51</td>
</tr>
</tbody>
</table>

`foreach lnname of varlist varlist` can be useful interactively but is rarely used in programming contexts. You can code

```
syntax [varlist] ...
foreach var of varlist 'varlist' {
    ...
}
```

but that is not as efficient as coding

```
syntax [varlist] ...
foreach var of local varlist {
    ...
}
```

because `varlist` has already been expanded by the `syntax` command according to the macro rules.

**Technical note**

```
syntax [varlist] ...
foreach var of local varlist {
    ...
}
```

is also preferable to

```
syntax [varlist] ...
tokenize 'varlist'
while "'1'" != "" {
    ...
    macro shift
}
```
foreach — Loop over items

or

    syntax [varlist] ...
    tokenize 'varlist'
    local i = 1
    while ""i"" != ""
    {
        ...
        local i = 'i' + 1
    }

because it is not only more readable but also faster.

foreach ... of newlist

newlist signifies to foreach that the list is composed of new variables. foreach verifies that
the list contains valid new variable names, but it does not create the variables. For instance,

    . foreach var of newlist z1-z4 {
        2. generate 'var' = runiform()
        3. }

would create variables z1, z2, z3, and z4.

foreach ... of numlist

foreach lname of numlist numlist provides a method of looping through a list of numbers.
Standard number-list notation is allowed; see [U] 11.1.8 numlist. For instance,

    . foreach num of numlist 1/4 8 103 {
        2. display 'num'
        3. }

1
2
3
4
8
103

If you wish to loop over many equally spaced values, do not code, for instance,

foreach x in 1/1000 {
    ...
}

Instead, code

    forvalues x = 1/1000 {
        ...
    }

foreach must store the list of elements, whereas forvalues obtains the elements one at a time by
calculation; see [P] forvalues.
Use of foreach with continue

The \textit{name} in \texttt{foreach} is defined only in the loop body. If you code

\begin{verbatim}
foreach x ... {
    // loop body, 'x' is defined
}
// 'x' is now undefined, meaning it contains ""
\end{verbatim}

'x' is defined only within the loop body, which is the case even if you use \texttt{continue}, \texttt{break} (see \texttt{\cite{P} continue}) to exit the loop early:

\begin{verbatim}
foreach x ... {
    ...
    if ... {
        continue, break
    }
}
// 'x' is still undefined, even if continue, break is executed
\end{verbatim}

If you later need the value of 'x', code

\begin{verbatim}
foreach x ... {
    ...
    if ... {
        local lastx "'x'"
        continue, break
    }
}
// 'lastx' defined
\end{verbatim}

The unprocessed list elements

The macro \texttt{ferest()} may be used in the body of the \texttt{foreach} loop to obtain the unprocessed list elements.

\textbf{Example 4}

\begin{verbatim}
   foreach x in alpha "one two" three four {
     2. display
     3. display "x is |'x'|"
     4. display "ferest() is |'ferest()'|
     5. }
   x is |alpha|
   ferest() is |"one two" three four|
     x is |one two|
   ferest() is |three four|
     x is |three|
   ferest() is |four|
     x is |four|
   ferest() is ||
\end{verbatim}
foreach — Loop over items

'ferest()' is available only within the body of the loop; outside that, 'ferest()' evaluates to "". Thus you might code

    foreach x ... {
        ... {
            local lastx ""x"
            local rest ""ferest()"
            continue, break
        }
    }

    // 'lastx' and 'rest' are defined

[P] if — if programming command
[P] levelsof — Levels of variable
[P] while — Looping
[U] 18 Programming Stata
[U] 18.3 Macros
forvalues — Loop over consecutive values

Description

forvalues repeatedly sets local macro lname to each element of range and executes the commands enclosed in braces. The loop is executed zero or more times.

Syntax

```
forvalues lname = range {
  Stata commands referring to `lname'
}
```

where `range` is

- `#1(#d)#2` meaning `#1` to `#2` in steps of `#d`
- `#1/#2` meaning `#1` to `#2` in steps of 1
- `#1 #i to #2` meaning `#1` to `#2` in steps of `#i - #1`
- `#1 #i : #2` meaning `#1` to `#2` in steps of `#i - #1`

The loop is executed as long as calculated values of `lname` are \leq #2, assuming that `#d > 0`.

Braces must be specified with `forvalues`, and

1. the open brace must appear on the same line as `forvalues`;
2. nothing may follow the open brace except, of course, comments; the first command to be executed must appear on a new line;
3. the close brace must appear on a line by itself.

Remarks and examples

forvalues is the fastest way to execute a block of code for different numeric values of lname.

Example 1

With `forvalues lname = #1(#d)#2`, the loop is executed zero or more times, once for `lname = #1`, once for `lname = #1 + #d`, once for `lname = #1 + #d + #d`, and so on, as long as `lname \leq #2` (assuming `#d` is positive) or as long as `lname \geq #2` (assuming `#d` is negative). Specifying `#d` as 0 is an error.

```
. forvalues i = 1(1)5 {
  2.       display 'i'
  3. }
1
2
3
4
5
```
lists the numbers 1–5, stepping by 1, whereas

```
. forvalues i = 10(-2)1 {
  2. display 'i'
  3. }
10
  8
  6
  4
  2
```

lists the numbers starting from 10, stepping down by 2 until it reaches 2. It stops at 2 instead of at 1 or 0.

```
. forvalues i = 1(1)1 {
  2. display 'i'
  3. }
1
```
displays 1, whereas

```
. forvalues i = 1(1)0 {
  2. display 'i'
  3. }
```
displays nothing.

```
forvalues lname = #1/#2 is the same as using forvalues lname = #1(1)#2. Using / does not allow counting backward.
```

Example 2

```
. forvalues i = 1/3 {
  2. display 'i'
  3. }
1
  2
  3
```
lists the three values from 1 to 3, but

```
. forvalues i = 3/1 {
  2. display 'i'
  3. }
```
lists nothing because using this form of the forvalues command allows incrementing only by 1.

The forvalues lname = #1 #i to #2 and forvalues lname = #1 #i : #2 forms of the forvalues command are equivalent to computing #d = #i − #1 and then using the forvalues lname = #1(#d)#2 form of the command.
Example 3

```
. forvalues i = 5 10 : 25 {
    2.    display 'i'
    3. }
5
10
15
20
25
. forvalues i = 25 20 to 5 {
    2.    display 'i'
    3. }
25
20
15
10
5
```

Technical note

It is not legal syntax to type

```
. scalar x = 3
. forvalues i = 1(1)'x' {
    2.    local x = 'x' + 1
    3.    display 'i'
    4. }
```

`forvalues` requires literal numbers. Using macros, as shown in the following technical note, is allowed.

```
. local n 3
. forvalues i = 1(1)'n' {
    2.    local n = 'n' + 1
    3.    display 'i'
    4. }
1
2
3
```

will not create an infinite loop. With `n` originally equal to 3, the loop will be performed three times.
Similarly, modifying the loop counter will not affect `forvalues' subsequent behavior. For instance,

```
. forvalues i = 1(1)3 {
  2.     display "Top of loop i = 'i'"
  3.     local i = 'i' * 4
  4.     display "After change i = 'i'"
  5. }
```

```
Top of loop i = 1
After change i = 4
Top of loop i = 2
After change i = 8
Top of loop i = 3
After change i = 12
```

will still execute three times, setting `i' to 1, 2, and 3 at the beginning of each iteration.

[U] 18.3 Macros
fvexpand — Expand factor varlists

Description

fvexpand expands a factor varlist to the corresponding expanded, specific varlist. varlist may be general or specific and even may already be expanded.

Syntax

fvexpand [ varlist ] [ if ] [ in ]

varlist may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

Remarks and examples

An example of a general factor varlist is mpg i.foreign. The corresponding specific factor varlist would be mpg i(0 1)b0.foreign if foreign took on the values 0 and 1 in the data.

A specific factor varlist is specific with respect to a given problem, which is to say, a given dataset and subsample. The specific varlist identifies the values taken on by factor variables and the base.

Factor varlist mpg i(0 1)b0.foreign is specific. The same varlist could be written as mpg i0b.foreign i1.foreign, so that is specific, too. The first is unexpanded and specific. The second is expanded and specific.

fvexpand takes a general or specific (expanded or unexpanded) factor varlist, along with an optional if or in, and returns a fully expanded, specific varlist.

Stored results

fvexpand stores the following in r():

Macros

\r(varlist) the expanded, specific varlist
\r(fvops) true if varlist contains factor variables
\r(tsops) true if varlist contains time-series operators

[U] 11.4.3 Factor variables
Description

gettoken is a low-level parsing command designed for programmers who wish to parse input for themselves. The syntax command (see \[P\] syntax) is an easier-to-use, high-level parsing command.

gettoken obtains the next token from the macro \texttt{emname3} and stores it in the macro \texttt{emname1}. If macro \texttt{emname2} is specified, the rest of the string from \texttt{emname3} is stored in the \texttt{emname2} macro. \texttt{emname1} and \texttt{emname3}, or \texttt{emname2} and \texttt{emname3}, may be the same name. The first token is determined based on the parsing characters \texttt{pchars}, which default to a space if not specified.

Syntax

\begin{verbatim}
gettoken \texttt{emname1} \[\texttt{emname2}] : \texttt{emname3} [ , \texttt{parse("pchars")} \texttt{quotes} 

\quad \texttt{qed(lmacname)} \texttt{match(lmacname)} \texttt{bind} ]
\end{verbatim}

where \texttt{pchars} are the parsing characters, \texttt{lmacname} is a local macro name, and \texttt{emname} is described in the following table:

<table>
<thead>
<tr>
<th>\texttt{emname} is ...</th>
<th>Refers to a ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>macroname</td>
<td>local macro</td>
</tr>
<tr>
<td>(local) macroname</td>
<td>local macro</td>
</tr>
<tr>
<td>(global) macroname</td>
<td>global macro</td>
</tr>
</tbody>
</table>

Options

\texttt{parse("pchars")} specifies the parsing characters. If \texttt{parse()} is not specified, \texttt{parse(" ")} is assumed, meaning tokens are identified by blanks.

\texttt{quotes} specifies that the outside quotes are not to be stripped in what is stored in \texttt{emname1}. This option has no effect on what is stored in \texttt{emname2} because it always retains outside quotes. \texttt{quotes} is a rarely specified option; usually you want the quotes stripped. You would not want the quotes stripped if you wanted to make a perfect copy of the contents of the original macro for parsing at a later time.

\texttt{qed(lmacname)} specifies a local macroname that is to be filled in with 1 or 0 according to whether the returned token was enclosed in quotes in the original string. \texttt{qed()} does not change how parsing is done; it merely returns more information.

\texttt{match(lmacname)} specifies that parentheses be matched in determining the token. The outer level of parentheses, if any, are removed before the token is stored in \texttt{emname1}. The local macro \texttt{lmacname} is set to “(" if parentheses were found; otherwise, it is set to an empty string.

\texttt{bind} specifies that expressions within parentheses and those within brackets are to be bound together, even when not parsing on () and [].

268
Remarks and examples

Often we apply \texttt{gettoken} to the macro `0` (see \cite{18.4.6 Parsing nonstandard syntax}), as in

\begin{verbatim}
gettoken first : 0
\end{verbatim}

which obtains the first token (with spaces as token delimiters) from `0` and leaves `0` unchanged. Or, alternatively,

\begin{verbatim}
gettoken first 0 : 0
\end{verbatim}

which obtains the first token from `0` and saves the rest back in `0`.

\begin{example}

Even though \texttt{gettoken} is typically used as a programming command, we demonstrate its use interactively:

\begin{verbatim}
 . local str "cat+dog mouse++horse"
 . gettoken left : str
 . display "'left'";
 cat+dog
 . display "'str'";
 cat+dog mouse++horse
 . gettoken left str : str, parse(" +")
 . display "'left'";
 cat
 . display "'str'";
 +dog mouse++horse
 . gettoken next str : str, parse(" +")
 . display "'next'";
 +
 . display "'str'";
 dog mouse++horse
\end{verbatim}

Both global and local variables may be used with \texttt{gettoken}. Strings with nested quotes are also allowed, and the \texttt{quotes} option may be specified if desired. For more information on compound double quotes, see \cite{18.3.5 Double quotes}.

\begin{verbatim}
 . global weird "'""some" strings"' are "'within "strings"'"
 . gettoken (local)left (global)right : (global)weird
 . display "'left'";
 "some" strings
 . display "'$right'";
 are "'within "strings"'"
 . gettoken left (global)right : (global)weird , quotes
 . display "'left'";
 "'""some" strings"'"
 . display "'$right'";
 are "'""within "strings"'"
\end{verbatim}

The \texttt{match()} option is illustrated below.
Example 2

One use of `gettoken` is to process two-word commands. For example, `mycmd list` does one thing and `mycmd generate` does another. We wish to obtain the word following `mycmd`, examine it, and call the appropriate subroutine with a perfect copy of what followed.

```
program mycmd
    version 15.0
    gettoken subcmd 0 : 0
    if "subcmd" == "list" {
        mycmd_l '0'
    }
    else if "subcmd" == "generate" {
        mycmd_g '0'
    }
    else error 199
end
```

```
program mycmd_l
    ...
end
```

```
program mycmd_g
    ...
end
```

Example 3

Suppose that we wish to create a general prefix command with the syntax

```
newcmd ... : stata_command
```

where `...` represents some possibly complicated syntax. We want to split this entire command line at the colon, making a perfect copy of what precedes the colon, which will be parsed by our program, and what follows the colon, which will be passed along to `stata_command`. 
gettoken — Low-level parsing  271

program newcmd
version 15.0
gettoken part 0 : 0, parse(" ") quotes
while "part" != ":" & "part" != "{" {
    local left "left" "part"
    gettoken part 0 : 0, parse(" ") quotes
}
('left' now contains what followed newcmd up to the colon)
('0' now contains what followed the colon)
...

end

Notice the use of the quotes option. We also used compound double quotes when accessing
‘part’ and ‘left’ because these macros might contain embedded quotation marks.

Technical note

We strongly encourage you to specify space as one of your parsing characters. For instance, with
the last example, you may have been tempted to use gettoken but to parse only on colon instead
of on colon and space, as in

gettoken left 0 : 0, parse(':') quotes
gettoken colon 0 : 0, parse(':')

and thereby avoid the while loop. This is not guaranteed to work for two reasons. First, if the length
of the string up to the colon is large, then you run the risk of having it truncated. Second, if ‘left’
begins with a quotation mark, then the result will not be what you expect.

Our recommendation is always to specify a space as one of your parsing characters and to grow
your desired macro as demonstrated in our last example.

Technical note

If one of the parsing characters specified is the equal sign, for example, parse("= "), then not
only is the equal sign treated as one token, but so is Stata’s equality operator, ==. For instance,
parsing “y=x if z==3” results in the tokens “y”, “=”, “x”, “if”, “z”, “==”, and “3”.

[U] 18 Programming Stata
Title

if — if programming command

Description

The if command (not to be confused with the if qualifier; see [U] 11.1.3 if exp) evaluates exp. If the result is true (nonzero), the commands inside the braces are executed. If the result is false (zero), those statements are ignored, and the statement (or statements if enclosed in braces) following the else is executed.

Syntax

if exp {
  multiple_commands
}
or

if exp single_command

which, in either case, may be followed by

total_command

else {
  multiple_commands
}
or

else single_command

If you put braces following the if or else,

1. the open brace must appear on the same line as the if or else;
2. nothing may follow the open brace except, of course, comments; the first command to be executed must appear on a new line;
3. the close brace must appear on a line by itself.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Avoid single-line if and else with ++ and -- macro expansion

Introduction

The if command is intended for use inside programs and do-files; see [U] 18.3.4 Macros and expressions for examples of its use.
Example 1

Do not confuse the if command with the if qualifier. Typing if (age>21) summarize age will summarize all the observations on age if the first observation on age is greater than 21. Otherwise, it will do nothing. Typing summarize age if age>21, on the other hand, summarizes all the observations on age that are greater than 21.

Example 2

if is typically used in do-files and programs. For instance, let’s write a program to calculate the Tukey (1977, 90–91) “power” function of a variable, x:

```stata
program power
    if ’2’>0 {
        generate z=’1’^’2’
        label variable z ”’1’^’2’”
    }
    else if ’2’==0 {
        generate z=log(’1’)
        label variable z ”log(’1’)”
    }
    else {
        generate z=-(’1’^’2’)
        label variable z ”-(’1’^’2’)”
    }
end
```

This program takes two arguments. The first argument is the name of an existing variable, x. The second argument is a number, which we will call n. The program creates the new variable z. If n > 0, z is $x^n$; if n = 0, z is log(x); and if n < 0, z is $-x^n$. No matter which path the program follows through the code, it labels the variable appropriately:

```
. power age 2
. describe z
```

Technical note

If the expression refers to any variables, their values in the first observation are used unless explicit subscripts are specified.

Avoid single-line if and else with ++ and -- macro expansion

Do not use the single-line forms of if and else—do not omit the braces—when the action includes the ‘++’ or ‘--’ macro-expansion operators. For instance, do not code

```stata
if (... somecommand ‘++i’
```
Code instead,

```plaintext
if (...) {
    somecommand ++i
}
```

In the first example, `i` will be incremented regardless of whether the condition is true or false because macro expansion occurs before the line is interpreted. In the second example, if the condition is false, the line inside the braces will not be macro expanded and so `i` will not be incremented.

The same applies to the `else` statement; do not code

```plaintext
else somecommand ++i
```

Code instead,

```plaintext
else {
    somecommand ++i
}
```

⚠️ Technical note

What was just said also applies to macro-induced execution of class programs that have side effects. Consider

```plaintext
if (...) somecommand .clspgm.getnext
```

Class-member program `.getnext` would execute regardless of whether the condition were true or false. Here code

```plaintext
if (...) {
    somecommand .clspgm.getnext
}
```

Understand that the problem arises only when macro substitution causes the invocation of the class program. There would be nothing wrong with coding

```plaintext
if (...) .clspgm.getnext
```

[U] 18 Programming Stata
Title

**include — Include commands from file**

<table>
<thead>
<tr>
<th>Description</th>
<th>Syntax</th>
<th>Option</th>
<th>Remarks and examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Also see</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

`include` is a variation on `do` and `run` that causes Stata to execute the commands stored in the specified file as if they were entered from the keyboard. `include` is for advanced programming to share common definitions among several do-files. `include` may also be used in Mata to create a library of routines with shared concepts.

Syntax

```
include filename [, adopath]
```

If `filename` is specified without an extension, `.do` is assumed.

Option

`adopath` indicates to search Stata’s system directories for `filename` if it is not found in the default location.

Remarks and examples

Remarks are presented under the following headings:

- Use with do-files
- Use with Mata
- Warning

Use with do-files

`include` can be used in advanced programming situations where you have several do-files among which you wish to share common definitions. `include` differs from `do` and `run` in that any local macros (changed settings, etc.) created by executing the file are not dropped or reset when execution of the file concludes. Rather, results are as if the commands in `filename` appeared in the session or file that included `filename`.

Say that you have do-files `step1.do`, `step2.do`, and `step3.do` that perform a data management task. You want the do-files to include a common definition of the local macros `inname` and `outname`, which are, respectively, the names of the files to be read and created. One way to do this is
Presumably, files *step1.do*, *step2.do*, and *step3.do* include lines such as

`. use 'inname', clear

and

`. save 'outname', replace

Our use of the *.doh* suffix in naming file *common.doh* is not a typo. We called the file *.doh* to emphasize that it is a header for do-files, but you can name the file as you wish, including *common.do*. You could call the file *common.do*, but you could not use the do command to run it because the local macros that the file defines would automatically be dropped when the file finished executing; thus in *step1.do*, *step2.do*, and *step3.do*, the macros would be undefined.

**Use with Mata**

`include` is sometimes used in advanced Mata situations where you are creating a library of routines with shared concepts:

```
version 15.0
include limits.matah
mata:
real matrix inpivot(real matrix X)
{
    real matrix y1, yz
    real scalar n
    if (rows(X)>`MAXDIM' | cols(X)>`MAXDIM') {
        errprintf("inpivot: matrix too large\n")
        exit(1000)
    }
    ...}
end
```
Presumably, many `.mata` files include `limits.mata`.

**Warning**

Do not use command `include` in the body of a Stata program:

```stata
test
    include ...
end
```

`include` will not be executed, as you might have hoped, when the program is compiled. Instead, `include` will be stored in your program and executed every time your program runs. The result will be the same as if the lines had been included at compile time, but the execution will be slower.

**Also see**

[R] do — Execute commands from a file

[R] doedit — Edit do-files and other text files
**Description**

Java plugins are Java programs that you can call from Stata. When called from Stata, a Java plugin can interact with Stata’s datasets, matrices, macros, scalars, and more. Programmers familiar with Java can use Java’s extensive language features. There are also many third-party libraries available. If you are not an experienced Java programmer and you intend to implement a Java plugin, you should start by learning Java. Once you become a proficient Java programmer, writing a Java plugin for Stata should be relatively easy.

**Remarks and examples**

A Java plugin is called or executed using Stata’s `javacall` command. For a Java plugin to be useful, it needs to have access to a set of Stata’s core features. Stata provides Java packages that allow plugins to interact with Stata; refer to Java-Stata API Specification for details. When compiling your Java plugin to use these features, the `sfi-api.jar` file needs to be added to the class-path of your Java compiler. This file is located in `utilities/jar/`, which can be found in the directory where Stata was installed.

Once Java source code has been compiled, a Java plugin can be executed from Stata by bundling your plugin in a JAR file and then placing the JAR file in Stata’s `ado-path`. See [P] `javacall` for examples and additional details about loading plugins.

Java plugins can be redistributed just like any other Stata program. To redistribute your Java plugin through Stata’s `net` command, you must bundle your compiled program into a JAR file because `net` copies `.class` files as text instead of binary. Additionally, you should always write a Stata ado-program as a wrapper to `javacall` to parse your syntax. The ado-program’s `version` command should always be set to match the Stata version from which you obtained the `sfi-api.jar` file that you compile against.

A typical Java standalone program has an entry point through a `main()` method, which looks like this:

```java
static void main(String[] args)
```

To call a Java plugin from Stata, you must define a similar entry point. However, there are two important distinctions. First, you may name your method whatever you like, as long as it conforms to standard Java naming requirements. Second, your method must have a return type of `int` instead of `void`. Here is an example of a valid method signature that Stata can call:

```java
static int mymethod(String[] args)
```

Let’s assume that `mymethod()` exists and that the compiled Java files have been placed in an appropriate location. To call `mymethod()`, we use Stata’s `javacall` command. `javacall` allows you to invoke any static method in the class-path if that method follows the correct signature as described above. For details on class-path behavior, see [P] `javacall`. 

278
Also see

[P] javacall — Call a Java plugin
javacall — Call a Java plugin

**Description**

javacall calls a Java plugin by invoking a static method. The *method* to be called must be implemented with a specific Java signature in the following form:

```java
static int java_method_name(String[] args)
```

javacall requires *class* to be a fully qualified name that includes the class’s package specification. For example, to call a method named `method1` from class `Class1`, which was part of package `com.mydomain` and packaged in `myjarfile.jar`, the following command would be used:

```
.javacall com.mydomain.Class1 method1, jars(myjarfile.jar)
```

Optionally, a varlist, an *if* condition, or an *in* condition may be specified. Stata provides a Java package containing various classes and methods allowing access to the varlist, *if* condition, and *in* condition; see [P java] for more details.

**Syntax**

```
javacall class method [varlist] [if] [in], {jars(jar_files) | classpath(classpath)} [args(arg_list)]
```

**Options**

- `jars(jar_files)` specifies the JAR files to be added to the class-path. *jar_files* may be one JAR file or a list of JAR files separated either by spaces or by semicolons. Stata will search along the ado-path for the specified JAR files and add them to the Java class-path for the plugin. Either `jars()` or `classpath()` must be specified.

- `classpath(classpath)` specifies the class-path to use. *classpath* may be a single class-path or multiple paths specified using a platform-specific Java class-path. On Windows, multiple paths are separated by semicolons. On Mac and Unix, multiple paths are separated by colons. Either `jars()` or `classpath()` must be specified.

This option is provided as a convenience for use during the development process. For example, a developer might use this option to set the class-path to the directory where their compiler is generating `.class` files, allowing newly compiled code to be tested quickly without the need to build a JAR file. After the development process is complete, a JAR file should be created, and the `jars()` option should be used instead.

- `args(arg_list)` specifies the *arg_list* that will be passed to the Java method as a string array. If `args()` is not specified, the array will be empty.
Remarks and examples

Each Java plugin uses its own instance of the class-loader, allowing the currently loaded plugin to be discarded and a new version of the plugin to be loaded. Because each plugin uses a separate instance of the class-loader, dependencies are not shared globally. A plugin developer can bundle their plugin with any third-party dependencies using a single JAR file, or dependencies may be distributed in multiple JAR files. Plugin isolation occurs because the jars() option allows each plugin to use a unique set of JAR files.

Example 1

Consider two variables needing to store integers too large to be held accurately in a double or a long, so instead they are stored as strings. If we needed to subtract the values in one variable from another, we could write a plugin using Java’s BigInteger class. The following code shows how we could perform the task:

```java
/* Java class begins here */
import java.math.BigInteger;
import com.stata.sfi.*;
class MyClass {
    /* Define the static method with the correct signature */
    public static int sub_string_vals(String[] args) {
        long nobs1 = Data.getObsParsedIn1();
        long nobs2 = Data.getObsParsedIn2();
        BigInteger b1, b2;
        if (Data.getParsedVarCount() != 2) {
            SFIToolkit.error("Exactly two variables must be specified\n");
            return(198);
        }
        if (args.length != 1) {
            SFIToolkit.error("New variable name not specified\n");
            return(198);
        }
        if (Data.addVarStr(args[0], 10)!=0) {
            SFIToolkit.errorln("Unable to create new variable " + args[0]) ;
            return(198) ;
        }
        // get the real indexes of the varlist
        int mapv1 = Data.mapParsedVarIndex(1) ;
        int mapv2 = Data.mapParsedVarIndex(2) ;
        int resv = Data.getVarIndex(args[0]) ;
        if (!Data.isVarTypeStr(mapv1) || !Data.isVarTypeStr(mapv2)) {
            SFIToolkit.error("Both variables must be strings\n");
            return(198) ;
        }
        for(long obs=nobs1; obs<=nobs2; obs++) {
            // Loop over the observations
            if (!Data.isParsedIfTrue(obs)) continue ;
            // skip any observations omitted from an [if] condition
            try {
                b1 = new BigInteger(Data.getStr(mapv1, obs)) ;
                b2 = new BigInteger(Data.getStr(mapv2, obs)) ;
                Data.storeStr(resv, obs, b1.subtract(b2).toString()) ;
            } catch (NumberFormatException e) { }
        }
        return(0) ;
    }
} /* Java class ends here */
```
Consider the following data, containing two string variables with four observations:

```
    . input str20 big1 str20 big2
          29811231010193176  29811231010193168
          42981123101023696  42981123101023669
         -98121437010116560 -98121437010116589
          1000                999
    end
    . list

                             big1             big2
         1.  29811231010193176   29811231010193168
         2.  42981123101023696   42981123101023669
         3. -98121437010116560 -98121437010116589
         4.      1000                999
```

Next we call the Java method using javacall. The two variables to subtract are passed in as a varlist, and the name of the new variable is passed in as a single argument using the args() option.

```
    . javacall MyClass sub_string_vals big1 big2, args(result1) jars(test.jar)
    . list

                             big1             big2            result1
         1.  29811231010193176   29811231010193168     8
         2.  42981123101023696   42981123101023669    27
         3. -98121437010116560 -98121437010116589    29
         4.      1000                999              1
```

Normally, a program should be used as a wrapper for javacall; see [U] 18 Programming Stata. For example,

```
program subtract_str
    version 15.0
    syntax varlist [if] [in], result(string)
    confirm new variable ‘result’
    javacall MyClass sub_string_vals ‘varlist’ ‘if’ ‘in’, ///
            args(‘result’) jars(test.jar)
end
```

```
    . subtract_str big1 big2, result(bigres)
    . list

                             big1             big2            bigres
         1.  29811231010193176   29811231010193168     8
         2.  42981123101023696   42981123101023669    27
         3. -98121437010116560 -98121437010116589    29
         4.      1000                999              1
```

[P] java — Java plugins
Description

`levelsof` displays a sorted list of the distinct values of `varname`.

Syntax

```
levelsof `varname' [if] [in] [ , options ]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clean</td>
<td>display string values without compound double quotes</td>
</tr>
<tr>
<td>local(<code>macname</code>)</td>
<td>insert the list of values in the local macro <code>macname</code></td>
</tr>
<tr>
<td>missing</td>
<td>include missing values of <code>varname</code> in calculation</td>
</tr>
<tr>
<td>separate(<code>separator</code>)</td>
<td>separator to serve as punctuation for the values of returned list; default is a space</td>
</tr>
</tbody>
</table>

Options

clean displays string values without compound double quotes. By default, each distinct string value is displayed within compound double quotes, as these are the most general delimiters. If you know that the string values in `varname` do not include embedded spaces or embedded quotes, this is an appropriate option. clean does not affect the display of values from numeric variables.

local(`macname`) inserts the list of values in local macro `macname` within the calling program’s space. Hence, that macro will be accessible after `levelsof` has finished. This is helpful for subsequent use, especially with foreach; see [P] foreach.

missing specifies that missing values of `varname` be included in the tabulation. The default is to exclude them.

separate(`separator`) specifies a separator to serve as punctuation for the values of the returned list. The default is a space. A useful alternative is a comma.

Remarks and examples

`levelsof` serves two different functions. First, it provides a compact list of the distinct values of `varname`. More commonly, it is useful when you desire to cycle through the distinct values of `varname` with (say) foreach; see [P] foreach. levelsof leaves behind a list in `r(levels)` that may be used in a subsequent command.

`levelsof` may hit the limits imposed by your Stata. However, it is typically used when the number of distinct values of `varname` is modest.
The terminology of levels of a factor has long been standard in experimental design. See Cochran and Cox (1957, 148), Fisher (1942), or Yates (1937, 5).

Example 1

```stata
use http://www.stata-press.com/data/r15/auto
(levelsof rep78)
1 2 3 4 5
.display "'r(levels)''
1 2 3 4 5
.levelsof rep78, miss local(mylevs)
1 2 3 4 5.
.display "'mylevs'"
1 2 3 4 5.
.levelsof rep78, sep(,)
1,2,3,4,5
.display "'r(levels)''
1,2,3,4,5
Showing value labels when defined:
.levelsof factor, local(levels)
.foreach l of local levels {
    . di "-> factor = 'label (factor) 'l'"
    . whatever if factor == 'l'
.
}
```

Stored results

`levelsof` stores the following in `r()`:

Macros

`r(levels)` list of distinct values

Acknowledgments

`levelsof` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the `Stata Journal` and author of `Speaking Stata Graphics`. He in turn thanks Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books `An Introduction to Modern Econometrics Using Stata` and `An Introduction to Stata Programming` and Nicholas Winter of the Department of Politics at the University of Virginia, for their input.

**Description**

`global` assigns strings to specified global macro names (`mnames`). `local` assigns strings to local macro names (`lclnames`). Both double quotes (" and ") and compound double quotes (‘" and '"') are allowed; see [U] 18.3.5 Double quotes. If the string has embedded quotes, compound double quotes are needed.

`tempvar` assigns names to the specified local macro names that may be used as temporary variable names in a dataset. When the program or do-file concludes, any variables with these assigned names are dropped.

`tempname` assigns names to the specified local macro names that may be used as temporary scalar or matrix names. When the program or do-file concludes, any scalars or matrices with these assigned names are dropped.

`tempfile` assigns names to the specified local macro names that may be used as names for temporary files. When the program or do-file concludes, any datasets created with these assigned names are erased.

`macro` manipulates global and local macros.

See [U] 18.3 Macros for information on macro substitution.

**Syntax**

```
global mname [ = exp | : extended_fcn | "[ string ]" | ‘"[ string ]’ ]
local lclname [ = exp | : extended_fcn | "[ string ]" | ‘"[ string ]’ ]
tempvar lclname [ lclname [ ... ] ]
tempname lclname [ lclname [ ... ] ]
tempfile lclname [ lclname [ ... ] ]
local { ++lclname | --lclname }
macro dir
macro drop { mname [ mname [ ... ] ] | mname* | all }
macro list [ mname [ mname [ ... ] ] | all ]
macro shift [ # ]
```

- Macro extended functions for parsing
- Macro expansion operators and function
- The tempvar, tempname, and tempfile commands
  - Temporary variables
  - Temporary scalars and matrices
  - Temporary files
- Manipulation of macros
- Macros as arguments

Macros are a tool used in programming Stata, and this entry assumes that you have read [U] 18 Programming Stata and especially [U] 18.3 Macros. This entry concerns advanced issues not previously covered.

Formal definition of a macro

A macro has a macro name and macro contents. Everywhere a punctuated macro name appears in a command—punctuation is defined below—the macro contents are substituted for the macro name.

Macros come in two types, global and local. Macro names are up to 32 characters long for global macros and up to 31 characters long for local macros. The contents of global macros are defined with the global command and those of local macros with the local command. Global macros, once defined, are available anywhere in Stata. Local macros exist solely within the program or do-file in which they are defined. If that program or do-file calls another program or do-file, the local macros previously defined temporarily cease to exist, and their existence is reestablished when the calling program regains control. When a program or do-file ends, its local macros are permanently deleted.

To substitute the macro contents of a global macro name, the macro name is typed (punctuated) with a dollar sign ($) in front. To substitute the macro contents of a local macro name, the macro name is typed (punctuated) with surrounding left and right single quotes (‘ ’). In either case, braces ({}') can be used to clarify meaning and to form nested constructions. When the contents of an undefined macro are substituted, the macro name and punctuation are removed, and nothing is substituted in its place.
For example,

The input ... is equivalent to ...

global a "myvar"
generate $a = oldvar
generate a = oldvar
local a "myvar"
generate 'a' = oldvar
generate a = oldvar
global a "newvar"
global i = 2
generate $a$i = oldvar
local a "newvar"
llocal i = 2
generate 'a''i' = oldvar
global b1 "newvar"
global i=1
generate ${b$i} = oldvar
local b1 "newvar"
llocal i=1
generate 'b''i'' = oldvar
global b1 "newvar"
global a "b"
global i = 1
generate $({a$i} = oldvar
local b1 "newvar"
llocal a "b"
llocal i = 1
generate 'a''i'' = oldvar

global a "b"
global i = 1
generate $a = oldvar
local a "b"
llocal i = 1
generate 'a' = oldvar

Global and local macro names

What we say next is an exceedingly fine point: global macro names that begin with an underscore are really local macros; this is why local macro names can have only 31 characters. The local command is formally defined as equivalent to global __. Thus the following are equivalent:

local x
global _x
local i=1
global _i=1
local name "Bill"
global _name "Bill"
local fmt : format myvar
global _fmt : format myvar
local 3 '2'
global _3 $2

tempvar is formally defined as equivalent to local name : tempvar for each name specified after tempvar. Thus

tempvar a b c

is equivalent to

local a : tempvar
local b : tempvar
local c : tempvar

which in turn is equivalent to

global _a : tempvar
global _b : tempvar
global _c : tempvar

tempfile is defined similarly.
### Macro assignment

When you type

```
. local name "something"
```
or

```
. local name "'something''
```

*something* becomes the contents of the macro. The compound double quotes (" and ") are needed when *something* itself contains quotation marks. When you type

```
. local name = something
```

*something* is evaluated as an expression, and the result becomes the contents of the macro. Note the presence and lack of the equal sign. That is, if you type

```
. local problem "2+2"
. local result = 2+2
```

then *problem* contains 2+2, whereas *result* contains 4.

Finally, when you type

```
. local name : something
```

*something* is interpreted as an extended macro function. (Note the colon rather than nothing or the equal sign.) Of course, all of this applies to *global* as well as to *local*.

```
local ++lclname, or local --lclname, is used to increment, or decrement, lclname.
```

For instance, typing

```
. local ++x
```

is equivalent to typing

```
. local x = 'x' + 1
```

### Macro extended functions

Macro extended functions are of the form

```
. local mname : ...
```

For instance,

```
. local x : type mpg
. local y : matsize
. local z : display %9.4f sqrt(2)
```

We document the macro extended functions below. Macro extended functions are typically used in programs, but you can experiment with them interactively. For instance, if you are unsure what ‘*local x : type mpg*’ does, you could type

```
. local x : type mpg
. display "'x'"
```

`int`
Macro extended function for extracting program properties

properties command
   returns the properties declared for command; see [P] program properties.

Macro extended functions for extracting data attributes

type varname
   returns the storage type of varname, which might be int, long, float, double, str1, str2, etc.

format varname
   returns the display format associated with varname, for instance, %9.0g or %12s.

value label varname
   returns the name of the value label associated with varname, which might be “” (meaning no label), or, for example, make, meaning that the value label’s name is make.

variable label varname
   returns the variable label associated with varname, which might be “” (meaning no label), or, for example, Repair Record 1978.

data label
   returns the dataset label associated with the dataset currently in memory, which might be “” (meaning no label), or, for example, 1978 Automobile Data. See [D] label.

sortedby
   returns the names of the variables by which the data in memory are currently sorted, which might be “” (meaning not sorted), or, for example, foreign mpg, meaning that the data are in the order of the variable foreign, and, within that, in the order of mpg (the order that would be obtained from the Stata command sort foreign mpg). See [D] sort.

label valuelabelname  
   returns the label value of # in valuelabelname. For instance, label forlab 1 might return Foreign cars if forlab were the name of a value label and 1 mapped to “Foreign cars”. If 1 did not correspond to any mapping within the value label, or if the value label forlab were not defined, 1 (the # itself) would be returned.

   #2 optionally specifies the maximum length of the label to be returned. If label forlab 1 would return Foreign cars, then label forlab 1 6 would return Foreig.

   maxlength specifies that, rather than looking up a number in a value label, label return the maximum length of the labelings. For instance, if value label yesno mapped 0 to no and 1 to yes, then its maxlength would be 3 because yes is the longest label and it has three characters.

   strict specifies that nothing is to be returned if there is no value label for #.

label (varname)  
   works exactly as the above, except that rather than specifying the valuelabelname directly, you indirectly specify it. The value label name associated with varname is used, if there is one. If not, it is treated just as if valuelabelname were undefined, and the number itself is returned.

constraint  
   gives information on constraints.

   constraint # puts constraint # in mname or returns “” if constraint # is not defined. constraint # for # < 0 is an error.
constraint dir returns an unsorted numerical list of those constraints that are currently defined. For example,

```
constraint 1 price = weight
constraint 2 mpg > 20
local myname : constraint 2
macro list _myname
_myname: mpg > 20
local aname : constraint dir
macro list _aname
_aname: 2 1
```

char `{ varname[] | varname[charname]}` or char `{ _dta[] | _dta[charname]}` returns information on the characteristics of a dataset; see `[P] char`. For instance,

```
char mpg[one] "this"
char mpg[two] "that"
local x : char mpg[one]
di "'x'"
this
local x : char mpg[nosuch]
di "'x'"
local x : char mpg[]
di "'x'"
two one
```

### Macro extended function for naming variables

`permname suggested_name [, length(#) )` returns a valid new variable name based on `suggested_name` in `mname`, where `suggested_name` must follow naming conventions but may be too long or correspond to an already existing variable. `length(#)` specifies the maximum length of the returned variable name, which must be between 8 and 32. `length(32)` is the default. For instance,

```
local myname : permname foreign
macro list _myname
_myname: foreign1
local aname : permname displacement, length(8)
macro list _aname
_aname: displac
```

### Macro extended functions for filenames and file paths

`adosubdir ["]filename[" ]` puts in `mname` the subdirectory in which Stata would search for this file along the ado-path. Typically, the directory name would be the first letter of `filename`. However, certain files may result in a different name depending on their extension.
dir "dir" \{ files | dirs | other \} "pattern", \[ \[ , nofail respectcase \] \]
puts in mname the specified files, directories, or entries that are neither files nor directories,
from directory dir and matching pattern pattern, where the pattern matching is defined by Stata’s
strmatch(s1, s2) function; see [FN] String functions. The quotes in the command are optional
but recommended, and they are nearly always required surrounding pattern. The returned string
will contain each of the names, separated one from the other by spaces and each enclosed in double
quotes. If mname is subsequently used in a quoted context, it must be enclosed in compound
double quotes: ‘“mname”’.

The nofail option specifies that if the directory contains too many filenames to fit into a macro,
rather than issuing an error, the filenames that fit into mname should be returned. nofail should
rarely, if ever, be specified.

In Windows only, the respectcase option specifies that dir respect the case of filenames when
performing matches. Unlike other operating systems, Windows has, by default, case-insensitive
filenames. respectcase is ignored in operating systems other than Windows.

For example,
local list : dir . files "*" makes a list of all regular files in the current directory. In list
might be returned "subjects.dta" "step1.do" "step2.do" "reest.ado".
local list : dir . files "s*", respectcase in Windows makes a list of all regular files
in the current directory that begin with a lowercase “s”. The case of characters in the filenames
is preserved. In Windows, without the respectcase option, all filenames would be converted to
lowercase before being compared with pattern and possibly returned.
local list : dir . dirs "*" makes a list of all subdirectories of the current directory. In list
might be returned "notes" "subpanel".
local list : dir . other "*" makes a list of all things that are neither regular files nor
directories. These files rarely occur and might be, for instance, Unix device drivers.
local list : dir \"mydir\data\" files "*" makes a list of all regular files that are to be
found in \mydir\data. Returned might be "example.dta" "make.do" "analyze.do".

It is the names of the files that are returned, not their full path names.
local list : dir "subdir" files "*" makes a list of all regular files that are to be found in
subdir of the current directory.

sysdir [STATA | BASE | SITE | PLUS | PERSONAL]
returns the various Stata system directory paths; see [P] sysdir. The path is returned with a trailing
separator; for example, sysdir STATA might return D:\PROGRAMS\STATA\.

sysdir dirname
returns dirname. This function is used to code local x : sysdir ‘dir’, where ‘dir’ might
contain the name of a directory specified by a user or a keyword, such as STATA or BASE. The
appropriate directory name will be returned. The path is returned with a trailing separator.

Macro extended function for accessing operating-system parameters

environment name
returns the contents of the operating system’s environment variable named name, or “” if name
is undefined.
Macro extended functions for names of stored results

\[ e(\text{scalars} | \text{macros} | \text{matrices} | \text{functions}) \]
returns the names of all the stored results in \( e() \) of the specified type, with the names listed one after the other and separated by one space. For instance, \( e(\text{scalars}) \) might return \( N \) \( ll_0 \) \( df_m \) \( chi2 \) \( r2 \) \( p \), meaning that scalar stored results \( e(N) \), \( e(ll_0) \), ... exist.

\[ r(\text{scalars} | \text{macros} | \text{matrices} | \text{functions}) \]
returns the names of all the stored results in \( r() \) of the specified type.

\[ s(\text{macros}) \]
returns the names of all the stored results in \( s() \) of type macro, which is the only type that exists within \( s() \).

\[ \text{all \{globals|scalars|matrices\} ["pattern"]} \]
puts in \( mname \) the specified globals, scalars, or matrices that match the pattern, where the matching is defined by Stata’s \text{strmatch}(s_1,s_2) \) function; see [FN] String functions.

\[ \text{all \{numeric|string\} scalars ["pattern"]} \]
puts in \( mname \) the specified numeric or string scalars that match the pattern, where the matching is defined by Stata’s \text{strmatch}(s_1,s_2) \) function; see [FN] String functions.

Macro extended function for formatting results

\[ \text{display ...} \]
returns the results from the \text{display} command. The \text{display} extended function is the \text{display} command, except that the output is rerouted to a macro rather than to the screen.

You can use all the features of \text{display} that make sense. That is, you may not set styles with \text{as style} because macros do not have colors, you may not use \text{_continue} to suppress going to a new line on the real display (it is not being displayed), you may not use \text{_newline} (for the same reason), and you may not use \text{_request} to obtain input from the console (because input and output have nothing to do with macro definition). Everything else works. See [P] \text{display}.

\text{Example:}
\[ \text{local x : display %9.4f sqrt(2)} \]

Macro extended function for manipulating lists

\[ \text{list ...} \]
fills in \( mname \) with the \text{macrolist_directive}, which specifies one of many available commands or operators for working with macros that contain lists; see [P] \text{macro lists}.

Macro extended functions related to matrices

In understanding the functions below, remember that the \text{fullname} of a matrix row or column is defined as \text{eqname:name}. For instance, \text{fullname} might be \text{outcome:weight}, and then the \text{eqname} is \text{outcome} and the \text{name} is \text{weight}. Or the \text{fullname} might be \text{gnp:L.cpi}, and then the \text{eqname} is \text{gnp} and the \text{name} is \text{L.cpi}. Or the \text{fullname} might be \text{mpg}, in which case the \text{eqname} is “” and the \text{name} is \text{mpg}. Or the \text{fullname} might be \text{gnp:1.south#1.smsa}, and then the \text{eqname} is \text{gnp} and the \text{name} is \text{1.south#1.smsa}. For more information, see [P] \text{matrix define}.

\[ \text{rownames matname} \]
returns the names of the rows of \text{matname}, listed one after another and separated by one space. As many names are listed as there are rows of \text{matname}. 

colnames matname
   is like rownames but returns the names of the columns.

rowfullnames matname
   returns the full names of the rows of matname, listed one after another and separated by one space. As many full names are listed as there are rows of matname.

colfullnames matname
   is like rowfullnames but returns the full names of the columns.

roweq matname [ , quoted ]
   returns the equation names of the columns of matname, listed one after another and separated by one space. As many names are listed as there are columns of matname. If the eqname of a column is blank, _ (underscore) is substituted. Thus roweq might return “Poor Poor Poor Average Average” for one matrix and “_ _ _ _ _” for another. quoted specifies that equation names be enclosed in double quotes.

coleq matname [ , quoted ]
   is like roweq but returns the equation names of the columns.

rownumb matname string
   returns the row number of matname that matches string.

colnumb matname string
   is like rownumb but returns the column number of matname.

roweqnumb matname string
   returns the row equation number of matname that matches string.

coleqnumb matname string
   is like roweqnumb but returns the column equation number of matname.

rownfreeparms matname
   returns the number of free parameters in rows of matname.

colnfreeparms matname
   returns the number of free parameters in columns of matname.

rowlfs matname
   returns the number of linear forms among the rows of matname.

colnlfs matname
   returns the number of linear forms among the columns of matname.

rowsof matname
   returns the number of rows of matname.

colsof matname
   returns the number of columns of matname.

rowvarlist matname
   returns the variable list corresponding to the rows of matname.

colvarlist matname
   returns the variable list corresponding to the columns of matname.

rowlfnames matname [ , quoted ]
   returns the list of names corresponding to the linear forms in the rows of matname.

collfnames matname [ , quoted ]
   returns the list of names corresponding to the linear forms in the columns of matname.
In all cases, *matname* may be either a Stata matrix name or a matrix stored in *e()* or *r()*, such as *e(b)* or *e(V)*.

**Macro extended function related to time-series operators**

*tsnorm string*

returns the canonical form of *string* when *string* is interpreted as a time-series operator. For instance, if *string* is `1d1`, then `L2D` is returned, or if *string* is `1.1d1`, then `L3D` is returned. If *string* is nothing, “” is returned.

*tsnorm string*, *varname*

returns the canonical form of *string* when *string* is interpreted as a time-series–operated variable. For instance, if *string* is `ldl.gnp`, then `L2D.gnp` is returned, or if *string* is `l.ldl.gnp`, then `L3D.gnp` is returned. If *string* is just a variable name, then the variable name is returned.

**Macro extended function for copying a macro**

*copy {local|global} mname*

returns a copy of the contents of *mname*, or an empty string if *mname* is undefined.

**Macro extended functions for parsing**

*word count string*

returns the number of tokens in *string*. A token is a word (characters separated by spaces) or set of words enclosed in quotes. Do not enclose *string* in double quotes because *word count* will return 1.

*word # of string*

returns the #th token of *string*. Do not enclose *string* in double quotes.

*piece #1 #2 of "string", nobreak]*

returns a piece of *string*. This macro extended function provides a smart method of breaking a string into pieces of roughly the specified display columns. #1 specifies which piece to obtain. #2 specifies the maximum number of display columns of each piece. Each piece is built trying to fill to the maximum number of display columns without breaking in the middle of a word. However, when a word takes more display columns than #2, the word will be split unless nobreak is specified. nobreak specifies that words not be broken, even if that would result in a string being displayed in more than #2 columns.

Compound double quotes may be used around *string* and must be used when *string* itself might contain double quotes.

*strlen {local|global} mname*

returns the length of the contents of *mname* in bytes. If *mname* is undefined, then 0 is returned. For instance,

```
. constraint 1 price = weight
. local myname : constraint 1
. macro list _myname
_myname price = weight
. local lmyname : strlen local myname
.lmyname: 14
```
ustrlen \{local|global\} mname
returns the length of the contents of \textit{mname} in Unicode characters. If \textit{mname} is undefined, then 0 is returned.

udstrlen \{local|global\} mname
returns the length of the contents of \textit{mname} in display columns. If \textit{mname} is undefined, then 0 is returned.

\texttt{subinstr local mname \textit{"from" \textit{"to"}}}
returns the contents of \textit{mname}, with the first occurrence of \textit{``from''} changed to \textit{``to''}.

\texttt{subinstr local mname \textit{"from" \textit{"to"}}, all}
does the same thing but changes all occurrences of \textit{``from''} to \textit{``to''}.

\texttt{subinstr local mname \textit{"from" \textit{"to"}}, word}
returns the contents of \textit{mname}, with the first occurrence of the word \textit{``from''} changed to \textit{``to''}. A word is defined as a space-separated token or a token at the beginning or end of the string.

\texttt{subinstr local mname \textit{"from" \textit{"to"}}, all word}
does the same thing but changes all occurrences of the word \textit{``from''} to \textit{``to''}.

\texttt{subinstr global mname ...}
is the same as the above but obtains the original string from the global macro \$\textit{mname} rather than from the local macro \textit{mname}.

\texttt{subinstr ... global mname ..., ..., count(\{global|local\} mname2)}
in addition to the usual, places a count of the number of substitutions in the specified global or in local macro \textit{mname2}.

\textbf{Example 1}

\begin{verbatim}
. local string "a or b or c or d"
. global newstr : subinstr local string "c" "sand"
. display "$newstr"
a or b or sand or d
. local string2 : subinstr global newstr "or" "and", all count(local n)
. display "'string2'"
a and b and sand and d
\end{verbatim}
The “and” in “sand” was not replaced by “x” because the word option was specified.

Macro expansion operators and function

There are five macro expansion operators that may be used within references to local (not global) macros.

`lclname++` and `++lclname` provide inline incrementation of local macro `lclname`. For example,

```stata
. local x 5
. display "'x++'"
5
. display "'x'"
6
```

`++` can be placed before `lclname`, in which case `lclname` is incremented before `lclname` is evaluated.

```stata
. local x 5
. display "'++x'"
6
. display "'x'"
6
```

`lclname--` and `--lclname` provide inline decrementation of local macro `lclname`.

`=exp` provides inline access to Stata’s expression evaluator. The Stata expression `exp` is evaluated and the result substituted. For example,

```stata
. local alpha = 0.05
. regress mpg weight, level('=100*(1-'alpha')')
```

`:extended_fcn` provides inline access to Stata’s extended macro functions. `:extended_fcn` evaluates to the results of the extended macro function `extended_fcn`. For example,

```stata
. format ':format gear_ratio' headroom
```

will set the display format of `headroom` to that of `gear_ratio`, which was obtained via the extended macro function `format`.

`.classDirective` provides inline access to class-object values. See `[P] class` for details.

The macro expansion function `macval(name)` expands local macro `name` but not any macros contained within `name`. For instance, if `name` contained “example ‘of’ macval”, `name` would expand to “example macval” (assuming that ‘of’ is not defined), whereas ‘macval(name)’ would expand to “example ‘of’ macval”. The ‘of’ would be left just as it is.

⚠️ Technical note

To store an unexpanded macro within another macro, use “\” to prevent macro expansion. This is useful when defining a formula with elements that will be substituted later in the program. To save the formula `sqrt('A' + 1)`, where ‘A’ is a macro you would like to fill in later, you would use the command

```stata
. local formula sqrt(\'A' + 1)
```
which would produce

```
   . macro list _formula
   _formula: sqrt('A' + 1)
```

Because the statement ‘\A’ was used, it prevented Stata from expanding the macro ‘A’ when it stored it in the macro ‘formula’.

Now you can fill in the macro ‘A’ with different statements and have this be reflected when you call ‘formula’.

```
   . local A 2^3
   . display "formula 'formula': " 'formula'
      formula sqrt(2^3 + 1): 3
   . local A log10(('A' + 2)^3)
   . display "formula 'formula': " 'formula'
      formula sqrt(log10((2^3 + 2)^3) + 1): 2
```

### The tempvar, tempname, and tempfile commands

The `tempvar`, `tempname`, and `tempfile` commands create names that may be used for temporary variables, temporary scalars and matrices, and temporary files. A temporary element exists while the program or do-file is running but, once it concludes, automatically ceases to exist.

#### Temporary variables

You are writing a program, and in the middle of it you need to calculate a new variable equal to \( \var1^2 + \var2^2 \) for use in the calculation. You might be tempted to write

```
   (code omitted)
   generate sumsq = var1^2 + var2^2
   (code continues)
   (code uses sumsq in subsequent calculations)
   drop sumsq
```

This would be a poor idea. First, users of your program might already have a variable called `sumsq`, and if they did, your program would break at the `generate` statement with the error “sumsq already defined”. Second, your program in the subsequent code might call some other program, and perhaps that program also attempts (poorly) to create the variable `sumsq`. Third, even if nothing goes wrong, if users press Break after your code executes `generate` but before `drop`, you would confuse them by leaving behind the `sumsq` variable.

The way around these problems is to use temporary variables. Your code should read

```
   (code omitted)
   tempvar sumsq
   generate 'sumsq' = var1^2 + var2^2
   (code continues)
   (code uses 'sumsq' in subsequent calculations)
   (you do not bother to drop 'sumsq')
```

The `tempvar sumsq` command creates a local macro called `sumsq` and stores in it a name that is different from any name currently in the data. Subsequently, you then use ‘`sumsq`’ with single quotes around it rather than `sumsq` in your calculation, so that rather than naming your temporary variable `sumsq`, you are naming it whatever Stata wants you to name it. With that small change, your program works just as before.
Another advantage of temporary variables is that you do not have to drop them—Stata will do that for you when your program terminates, regardless of the reason for the termination. If a user presses Break after the `generate`, your program is stopped, the temporary variables are dropped, and things really are just as if the user had never run your program.

**Technical note**

What do these temporary variable names assigned by Stata look like? It should not matter to you; however they look, they are guaranteed to be unique (`tempvar` will not hand out the same name to more than one concurrently executing program). Nevertheless, to satisfy your curiosity,

```
.tempvar var1 var2
.display "'var1' 'var2'"
. 000009 .00000A
```

Although we reveal the style of the names created by `tempvar`, you should not depend on this style. All that is important is that

- The names are unique; they differ from one call to the next.
- You should not prefix or suffix them with additional characters.
- Stata keeps track of any names created by `tempvar` and, when the program or do-file ends, searches the data for those names. Any variables found with those names are automatically dropped. This happens regardless of whether your program ends with an error.

**Temporary scalars and matrices**

`tempname` is the equivalent of `tempvar` for obtaining names for scalars and matrices. This use is explained, with examples, in `[P] scalar`.

**Technical note**

The temporary names created by `tempname` look just like those created by `tempvar`. The same cautions and features apply to `tempname` as `tempvar`:

- The names are unique; they differ from one call to the next.
- You should not prefix or suffix them with additional characters.
- Stata keeps track of any names created by `tempname` and, when the program or do-file ends, searches for scalars or matrices with those names. Any scalars or matrices so found are automatically dropped; see `[P] scalar`. This happens regardless of whether your program ends with an error.

**Temporary files**

`tempfile` is the equivalent of `tempvar` for obtaining names for disk files. Before getting into that, let’s discuss how you should not use `tempfile`. Sometimes, in the midst of your program, you will find it necessary to destroy the user’s data to obtain your desired result. You do not want to change the data, but it cannot be helped, and therefore you would like to arrange things so that the user’s original data are restored at the conclusion of your program.
You might then be tempted to save the user’s data in a (temporary) file, do your damage, and then restore the data. You can do this, but it is complicated, because you then have to worry about the user pressing Break after you have stored the data and done the damage but have not yet restored the data. Working with capture (see [P] capture), you can program all of this, but you do not have to. Stata’s preserve command (see [P] preserve) will handle saving and restoring the user’s data, regardless of how your program ends.

Still, there may be times when you need temporary files. For example,

```stata
preserve // preserve user’s data
keep var1 var2 xvar
save master, replace
drop var2
save part1, replace
use master, clear
drop var1
rename var2 var1
append using part1
erase master.dta
erase part1.dta
```

This is poor code, even though it does use preserve so that, regardless of how this code concludes, the user’s original data will be restored. It is poor because datasets called master.dta and part1.dta might already exist, and, if they do, this program will replace the user’s (presumably valuable) data. It is also poor because, if the user presses Break before both (temporary) datasets are erased, they will be left behind to consume (presumably valuable) disk space.

Here is how the code should read:

```stata
preserve // preserve user’s data
keep var1 var2 xvar
tempfile master part1 // declare temporary files
save "'master'"
drop var2
save "'part1'"
use "'master'", clear
drop var1
rename var2 var1
append using "'part1'"
```

In this version, Stata was asked to provide the names of temporary files in local macros named master and part1. We then put single quotes around master and part1 wherever we referred to them so that, rather than using the names master and part1, we used the names Stata handed us. At the end of our program, we no longer bother to erase the temporary files. Because Stata gave us the temporary filenames, it knows that they are temporary and erases them for us if our program completes, has an error, or the user presses Break.

Technical note

What do the temporary filenames look like? Again it should not matter to you, but for the curious,

```stata
.tempfile file1 file2
.display "‘file1’ ‘file2’"
/tmp/St13310.0001 /tmp/St13310.0002
```
We were using the Unix version of Stata; had we been using the Windows version, the last line might read

```
  . display "'file1' 'file2'"
  C:\WIN\TEMP\ST_0a00000c.tmp C:\WIN\TEMP\ST_00000d.tmp
```

Under Windows, Stata uses the environment variable TEMP to determine where temporary files are to be located. This variable is typically set in your autoexec.bat file. Ours is set to C:\WIN\TEMP. If the variable is not defined, Stata places temporary files in your current directory.

Under Unix, Stata uses the environment variable TMPDIR to determine where temporary files are to be located. If the variable is not defined, Stata locates temporary files in /tmp.

Although we reveal the style of the names created by `tempfile`, just as with `tempvar`, you should not depend on it. `tempfile` produces names the operating system finds pleasing, and all that is important is that

- The names are unique; they differ from one call to the next.
- You should assume that they are so long that you cannot prefix or suffix them with additional characters and make use of them.
- Stata keeps track of any names created by `tempfile`, and, when your program or do-file ends, looks for files with those names. Any files found are automatically erased. This happens regardless of whether your program ends with an error.

### Manipulation of macros

`macro dir` and `macro list` list the names and contents of all defined macros; both do the same thing:

```
  . macro list
  S_FNDATE: 13 Apr 2016 17:45
  S_FN: C:\Program Files\Stata15\ado\base/a/auto.dta
tofname: str18
  S_level: 95
  F1: help advice;
  F2: describe;
  F7: save
  F8: use
  S_ADO: BASE;SITE;.;PERSONAL;PLUS;OLDPLACE
  S_StataMP: MP
  S_StataSE: SE
  S_FLAVOR: Intercooled
  S_OS: Windows
  S_OSDTL: 64-bit
  S_MACH: PC (64-bit x86-64)
  _file2: C:\WIN\Temp\ST_0a00000d.tmp
  _file1: C:\WIN\Temp\ST_0a00000c.tmp
  _var2: __00000A
  _var1: __000009
  _str3: a x b x sand x d
  _dl: Employee Data
  _lb1: Employee name
  _vl: sexlbl
  _fmt: %9.0g
```
macro drop eliminates macros from memory, although it is rarely used because most macros are local and automatically disappear when the program ends. Macros can also be eliminated by defining their contents to be nothing using global or local, but macro drop is more convenient.

Typing macro drop base* drops all global macros whose names begin with base.

Typing macro drop _all eliminates all macros except system macros—those with names that begin with “S_”.

Typing macro drop S_* does not drop all system macros that begin with “S_”. It leaves certain macros in place that should not be casually deleted.

Example 2

```
  . macro drop _var* _lbl tofname _fmt
  . macro list
  S_FNDATE: 13 Apr 2016 17:45
  S_FN: C:\Program Files\Stata15\ado\base\a\auto.dta
  S_level: 95
  F1: help advice;

```
Technical note

Stata usually requires that you explicitly drop something before redefining it. For instance, before redefining a value label with the `label define` command or redefining a program with the `program define` command, you must type `label drop` or `program drop`. This way, you are protected from accidentally replacing something that might require considerable effort to reproduce.

Macros, however, may be redefined freely. It is not necessary to drop a macro before redefining it. Macros typically consist of short strings that could be easily reproduced if necessary. The inconvenience of the protection is not justified by the small benefit.

Macros as arguments

Sometimes programs have in a macro a list of things—numbers, variable names, etc.—that you wish to access one at a time. For instance, after parsing (see [U] 18.4 Program arguments), you might have in the local macro `varlist` a list of variable names. The `tokenize` command (see [P] tokenize) will take any macro containing a list and assign the elements to local macros named `'1'`, `'2'`, and so on. That is, if `varlist` contained “`mpg weight displ`”, then coding

```
tokenize 'varlist'
```

will make `'1'` contain “`mpg`”, `'2'` contain “`weight`”, `'3'` contain “`displ`”, and `'4'` contain “” (nothing). The empty fourth macro marks the end of the list.

`macro shift` can be used to work through these elements one at a time in constructs like

```
while "'1'" != '""' {
    do something based on '1'
    macro shift
}
```

`macro shift` discards `'1'`, shifts `'2'` to `'1'`, `'3'` to `'2'`, and so on. For instance, in our example, after the first `macro shift`, `'1'` will contain “`weight`”, `'2'` will contain “`displ`”, and `'3'` will contain “” (nothing).

It is better to avoid `macro shift` and instead code

```
local i = 1
while ""'i'"" != '""' {
    do something based on 'i'
    local i = 'i' + 1
}
```

This second approach has the advantage that it is faster. Also what is in `'1'`, `'2'`, ... remains unchanged so that you can pass through the list multiple times without resetting it (coding “`tokenize 'varlist'`” again).

It is even better to avoid `tokenize` and the numbered macros altogether and to instead loop over the variables in `varlist` directly:

```
foreach var of local varlist {
    do something based on 'var'
}
```

This is easier to understand and executes even more quickly; see [P] foreach.

`macro shift #` performs multiple macro shifts, or if `#` is 0, none at all. That is, `macro shift 2` is equivalent to two `macro shift` commands. `macro shift 0` does nothing.

Also see [P] macro lists for other list-processing commands.

*Stata Functions Reference Manual*
**Description**

The extended macro function list manipulates lists. See [P] macro for other extended macro functions.

uniq $A$ returns $A$ with duplicate elements removed. The resulting list has the same ordering of its elements as $A$; duplicate elements are removed from their rightmost position. If $A = "a b a c a \"$, uniq returns “a b c”.

dups $A$ returns the duplicate elements of $A$. If $A = "a b a c a \"$, dups returns “a a”.

sort $A$ returns $A$ with its elements placed in alphabetical (ascending ASCII or code-point) order.

clean $A$ returns $A$ retokenized and with each element adorned minimally. An element is said to be unadorned if it is not enclosed in quotes (for example, “a”). An element may also be adorned in simple or compound quotes (for example, "a" or ‘"a"’). Logically speaking, it makes no difference how elements are adorned, assuming that they are adorned adequately. The list

```
"a", "b c", "b "c" d"
```

is equal to

```
a "b c" "b "c" d"
```

clean, in addition to performing the actions of retokenize, adorns each element minimally: not at all if the element contains no spaces or quotes, in simple quotes (" and ") if it contains spaces but not quotes, and in compound quotes (‘" and "’) otherwise.

$A | B$ returns the union of $A$ and $B$, the result being equal to $A$ with elements of $B$ not found in $A$ added to the tail. For instance, if $A = "a b c \"$ and $B = "b d e \"$, $A | B$ is “a b c d e”. If you instead want list concatenation, you code,

```
local newlist '"A' 'B"'
```

In the example above, this would return “a b c b d e”.

$A \& B$ returns the intersection of $A$ and $B$. If $A = "a b c d \"$ and $B = "b c f g \"$, then $A \& B = "b c \"$.

$A - B$ returns a list containing elements of $A$ with the elements of $B$ removed, with the resulting elements in the same order as $A$. For instance, if $A = "a b c d \"$ and $B = "b e \"$, the result is “a c d”.

$A == B$ returns 0 or 1; it returns 1 if $A$ is equal to $B$, that is, if $A$ has the same elements as $B$ and in the same order. Otherwise, 0 is returned.

$A === B$ returns 0 or 1; it returns 1 if $A$ is equivalent to $B$, that is, if $A$ has the same elements as $B$ regardless of the order in which the elements appear. Otherwise, 0 is returned.
A in B returns 0 or 1; it returns 1 if all elements of A are found in B. If A is empty, in returns 1. Otherwise, 0 is returned.

sizeof A returns the number of elements of A. If A = “a b c”, sizeof A is 3. (sizeof returns the same result as the extended macro function word count; see Macro extended functions for parsing under Syntax in [P] macro.)

posof "element" in A returns the location of macname in A or returns 0 if not found. For instance, if A contains “a b c d”, then posof "b" in A returns 2. (word # of may be used to extract positional elements from lists, as can tokenize and gettoken; see Macro extended functions for parsing under Syntax in [P] macro and also see [P] tokenize and [P] gettoken.)

It is the element itself and not a macroname that you type as the first argument. In a program where macro tofind contained an element to be found in list (macro) variables, you might code

```plaintext
local i : list posof "'tofind'" in variables
```

This example shows the importance of quotations in specifying macronames. The element above must be enclosed in simple or compound quotes.

Syntax

```plaintext
{local | global} macname : list uniq macname
{local | global} macname : list dups macname
{local | global} macname : list sort macname
{local | global} macname : list retokenize macname
{local | global} macname : list clean macname
{local | global} macname : list macname | macname
{local | global} macname : list macname & macname
{local | global} macname : list macname - macname
{local | global} macname : list macname == macname
{local | global} macname : list macname === macname
{local | global} macname : list macname in macname
{local | global} macname : list sizeof macname
{local | global} macname : list posof "element" in macname
```

Note: Where macname appears above, it is the name of a macro and not its contents that you are to type. For example, you are to type

```plaintext
local result : list list1 | list2
```
and not

\textbf{local result : list "'list1'" | "'list2'"}

\textit{macnames} that appear to the right of the colon are assumed to be the names of local macros. You may type \texttt{local(macname)} to emphasize that fact. Type \texttt{global(macname)} if you wish to refer to a global macro.

**Remarks and examples**

Remarks are presented under the following headings:

- Treatment of adornment
- Treatment of duplicate elements in lists

A \textit{list} is a space-separated set of elements listed one after the other. The individual elements may be enclosed in quotes, and elements containing spaces obviously must be enclosed in quotes. The following are examples of lists:

\begin{verbatim}
this that what
"first element" second "third element" 4
this that what this that
\end{verbatim}

Also a list could be empty.

Do not confuse varlist with list. Varlists are a special notation, such as \texttt{"id m* pop*"}, which is a shorthand way of specifying a list of variables; see [U] 11.4 varname and varlists. Once expanded, however, a varlist is a list.

**Treatment of adornment**

An element of a list is said to be adorned if it is enclosed in quotes. Adornment, however, plays no role in the substantive interpretation of lists. The list

\begin{verbatim}
a "b" c
\end{verbatim}

is identical to the list

\begin{verbatim}
a b c
\end{verbatim}

**Treatment of duplicate elements in lists**

With the exception of uniq and dups, all list functions treat duplicates as being distinct. For instance, consider the list \texttt{A},

\begin{verbatim}
a b c b
\end{verbatim}

Notice that \texttt{b} appears twice in this list. You want to think of the list as containing \texttt{a}, the first occurrence of \texttt{b}, \texttt{c}, and the second occurrence of \texttt{b}:

\begin{verbatim}
a b1 c b2
\end{verbatim}

Do the same thing with the duplicate elements of all lists, carry out the operation on the now unique elements, and then erase the subscripts from the result.
If you were to ask whether \( B = “b b” \) is in \( A \), the answer would be yes, because \( A \) contains two occurrences of \( b \). If \( B \) contained \( “b b b” \), however, the answer would be no because \( A \) does not contain three occurrences of \( b \).

Similarly, if \( B = “b b” \), then \( A \mid B = “a b c b” \), but if \( B = “b b b” \), then \( A \mid B = “a b c b b” \).

[P] **macro** — Macro definition and manipulation
**makecns — Constrained estimation**

**Description**

`makecns` is a programmer’s command that facilitates adding constraints to estimation commands. `makecns` will create a constraint matrix and displays a note for each constraint that is dropped because of an error. The constraint matrix is stored in `e(Cns)`. `matcproc` returns matrices helpful for performing constrained estimation, including the constraint matrix.

If your interest is simply in using constraints in a command that supports constrained estimation, see [R] `constraint`.

**Syntax**

**Build constraints**

```
makecns [ clist | matname ] [ , options ]
```

**Create constraint matrix**

```
matcproc T a C
```

where `clist` is a list of constraint numbers, separated by commas or dashes; `matname` is an existing matrix representing the constraints and must have one more column than the `e(b)` and `e(V)` matrices.

T, a, and C are names of new or existing matrices.

**Options**

**Examples**
Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Overview
- Mathematics
- Linkage of the mathematics to Stata

Introduction

Users of estimation commands that allow constrained estimation define constraints with the `constraint` command; they indicate which constraints they want to use by specifying the `constraints(clist)` option to the estimation command. This entry concerns programming such sophisticated estimators. If you are programming using `ml`, you can ignore this entry. Constraints are handled automatically (and if you were to look inside the `ml` code, you would find that it uses `makecns`).

Before reading this entry, you should be familiar with constraints from a user’s perspective; see 

- [R] constraint. You should also be familiar with programming estimation commands that do not include constraints; see [P] `ereturn`.

Overview

You have an estimation command and wish to allow a set of linear constraints to be specified for the parameters by the user and then to produce estimates subject to those constraints. Stata will do most of the work for you. First, it will collect the constraints—all you have to do is add an option to your estimation command to allow the user to specify which constraints to use. Second, it will process those constraints, converting them from algebraic form (such as `group1=group2`) to a constraint matrix. Third, it will convert the constraint matrix into two matrices that will, for maximum likelihood estimation, allow you to write your routine almost as if there were no constraints.

There will be a “reduced-form” parameter vector, \( b_c \), which your likelihood-calculation routine will receive. That vector, multiplied by one of the almost magical matrices and then added to the other, can be converted into a regular parameter vector with the constraints applied, so other than the few extra matrix calculations, you can calculate the likelihood function as if there were no constraints. You can do the same thing with respect to the first and second derivatives (if you are calculating them), except that, after getting them, you will need to perform another matrix multiplication or two to convert them into the reduced form.

Once the optimum is found, you will have reduced-form parameter vector \( b_c \) and variance–covariance matrix \( V_c \). Both can be easily converted into full-form-but-constrained \( b \) and \( V \).

Finally, you will `ereturn post` the results along with the constraint matrix Stata made up for you in the first place. You can, with a few lines of program code, arrange it so that, every time results are replayed, the constraints under which they were produced are redisplayed in standard algebraic format.

Mathematics

Let \( Rb' = r \) be the constraint for \( R \), a \( c \times p \) constraint matrix imposing \( c \) constraints on \( p \) parameters; \( b \), a \( 1 \times p \) parameter vector; and \( r \), a \( c \times 1 \) vector of constraint values.
We wish to construct a $p \times k$ matrix, $T$, that takes $b$ into a reduced-rank form, where $k = p - c$. There are obviously many $T$ matrices that will do this; we choose one with the properties

$$b_c = b_0 T$$
$$b = b_c T' + a$$

where $b_c$ is a reduced-form projection of any solution $b_0$; that is, $b_c$ is a vector of lesser dimension ($1 \times k$ rather than $1 \times p$) that can be treated as if it were unconstrained. The second equation says that $b_c$ can be mapped back into a higher-dimensioned, properly constrained $b$; $1 \times p$ vector $a$ is a constant that depends only on $R$ and $r$.

With such a $T$ matrix and $a$ vector, you can engage in unconstrained optimization of $b_c$. If the estimate $b_c$ with variance–covariance matrix $V_c$ is produced, it can be mapped back into $b = b_c T' + a$ and $V = TV_c T'$. The resulting $b$ and $V$ can then be posted.

⚠️ Technical note

So, how did we get so lucky? This happy solution arises if

$$T = \text{first } k \text{ eigenvectors of } I - R'(RR')^{-1}R \quad (p \times k)$$
$$L = \text{last } c \text{ eigenvectors of } I - R'(RR')^{-1}R \quad (p \times c)$$
$$a = r'(L'R')^{-1}L'$$

because

$$(b_c, r') = b(T, R')$$

If $R$ consists of a set of consistent constraints, then it is guaranteed to have rank $c$. Thus $RR'$ is a $c \times c$ invertible matrix.

We will now show that $RT = 0$ and $R(LL') = R$.

Because $R: c \times p$ is assumed to be of rank $c$, the first $k$ eigenvalues of $P = I - R'(RR')^{-1}R$ are positive and the last $c$ are zero. Break $R$ into a basis spanned by these components. If $R$ had any components in the first $k$, they could not be annihilated by $P$, contradicting

$$RP = R - RR'(RR')^{-1}R = 0$$

Therefore, $T$ and $R$ are orthogonal to each other. Because $(T, L)$ is an orthonormal basis, $(T, L)'$ is its inverse, so $(T, L)(T, L)' = I$. Thus

$$TT' + LL' = I$$
$$(TT' + LL')R' = R'$$
$$(LL'R') = R'$$

So we conclude that $r = bR(LL')$. $RL$ is an invertible $c \times c$ matrix, so

$$\{b_c, r'(L'R)^{-1}\} = b(T, L)$$

Remember, $(T, L)$ is a set of eigenvectors, meaning $(T, L)^{-1} = (T, L)'$, so $b = b_c T' + r'(L'R)^{-1}L'$.
If a solution is found by likelihood methods, the reduced-form parameter vector is passed to the maximizer and from there to the program that computes a likelihood value from it. To find the likelihood value, the inner routines can compute $b = b_c T' + a$. The routine may then go on to produce a set of $1 \times p$ first derivatives, $d$, and $p \times p$ second derivatives, $H$, even though the problem is of lesser dimension. These matrices can be reduced to the $k$-dimensional space via

$$d_c = dT$$

$$H_c = T'HT$$

**Technical note**

Alternatively, if a solution were to be found by direct matrix methods, the programmer must derive a new solution based on $b = b_c T' + a$. For example, the least-squares normal equations come from differentiating $(y - Xb)^2$. Setting the derivative with respect to $b$ to zero results in

$$T'X'\left\{y - X(Tb'_c + a')\right\} = 0$$

yielding

$$b'_c = (T'X'XT)^{-1}(T'X'y - T'X'Xa')$$

$$b' = T\left\{(T'X'XT)^{-1}(T'X'y - T'X'Xa')\right\} + a'$$

Using the matrices $T$ and $a$, the solution is not merely to constrain the $b'$ obtained from an unconstrained solution $(X'X)^{-1}X'y$, even though you might know that, here, with further substitutions this could be reduced to

$$b' = (X'X)^{-1}X'y + (X'X)^{-1}R'(R(X'X)^{-1}R')^{-1}\{r - R(X'X)^{-1}X'y\}$$

**Linkage of the mathematics to Stata**

Users define constraints using the `constraint` command; see [R] `constraint`. The constraints are numbered, and Stata stores them in algebraic format—the same format in which the user typed them. Stata does this because, until the estimation problem is defined, it cannot know how to interpret the constraint. Think of the constraint $b[group1] = b[group2]$, meaning that two coefficients are to be constrained to equality, along with the constraint $b[group3] = 2$. The constraint matrices $R$ and $r$ are defined so that $Rb' = r$ imposes the constraint. The matrices *might* be

$$\begin{pmatrix} 0 & 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \\ b_5 \\ b_6 \end{pmatrix} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}$$

if it just so happened that the third and fourth coefficients corresponded to `group1` and `group2` and the fifth corresponded to `group3`. Then again, it might look different if the coefficients were organized differently.
Therefore, Stata must wait until estimation begins to define the $R$ and $r$ matrices. Stata learns about the organization of a problem from the names bordering the coefficient vector and variance–covariance matrix. Therefore, Stata requires you to `ereturn post` a dummy estimation result that has the correct names. From that, it can now determine the organization of the constraint matrix and make it for you. Once an (dummy) estimation result has been posted, `makecns` can make the constraint matrices, and, once they are built, you can obtain copies of them from `e(Cns)`. Stata stores the constraint matrices $R$ and $r$ as a $c \times (p + 1)$ matrix $C = (R, r)$. Putting them together makes it easier to pass them to subroutines.

The second step in the process is to convert the constrained problem to a reduced-form problem. We outlined the mathematics above; the `matcproc` command will produce the $T$ and $a$ matrices. If you are performing maximum likelihood, your likelihood, gradient, and Hessian calculation subroutines can still work in the full metric by using the same $T$ and $a$ matrices to translate the reduced-format parameter vector back to the original metric. If you do this, and if you are calculating gradients or Hessians, you must remember to compress them to reduced form using the $T$ and $a$ matrices.

When you have a reduced-form solution, you translate this back to a constrained solution using $T$ and $a$. You then `ereturn post` the constrained solutions, along with the original `Cns` matrix, and use `ereturn display` to display the results.

Thus the outline of a program to perform constrained estimation is

```
program myest, eclass properties(...)
version 15.0
if replay() { // replay the results
  if ("e(cmd)" != "myest") error 301
  syntax [, Level(cilevel) ]
  makecns , displaycns
} else { // fit the model
  syntax whatever [, //
    whatever //
    Constraints(string) //
    Level(cilevel) //
  ]
  // any other parsing of the user’s estimate request
  tempname b V C T a bc Vc
  local p=number of parameters
  // define the model (set the row and column names) in ‘b’
  if "‘constraints’" != ""
    matrix ‘V’ = ‘b’*‘b’
    ereturn post ‘b’ ‘V’ // a dummy solution
    makecns ‘constraints’, display
    matcproc ‘T’ ‘a’ ‘C’, // obtain solution in ‘bc’ and ‘Vc’
    matrix ‘b’ = ‘bc’*‘T’ + ‘a’
    matrix ‘V’ = ‘T’*‘Vc’*‘T’’, // note prime
    ereturn post ‘b’ ‘V’ ‘C’, options
  }
  else {
    // obtain standard solution in ‘b’ and ‘V’
    ereturn post ‘b’ ‘V’, options
  }
  // store whatever else you want in e()
  ereturn local cmd "myest"
  // output any header above the coefficient table
  ereturn display, level(‘level’)
end
```
There is one point that might escape your attention: Immediately after obtaining the constraint, we display the constraints even before we undertake the estimation. This way, a user who has made a mistake may press Break rather than waiting until the estimation is complete to discover the error. Our code displays the constraints every time the results are reported, even when typing myest without arguments.

 Stored results

makecns stores the following in r():

Scalars
   r(k_autoCns) number of base, empty, and omitted constraints

Macros
   r(clist) constraints used (numlist or matrix name)

<table>
<thead>
<tr>
<th>Description</th>
<th>Syntax Options</th>
<th>Remarks and examples</th>
</tr>
</thead>
</table>

**Description**

*marksample, mark, and markout* are for use in Stata programs. *marksample* and *mark* are alternatives; *marksample* links to information left behind by *syntax*, and *mark* is seldom used. Both create a 0/1 to-use variable that records which observations are to be used in subsequent code. *markout* sets the to-use variable to 0 if any variables in *varlist* contain missing and is used to further restrict observations.

*markin* is for use after *marksample, mark, and markout* and, sometimes, provides a more efficient encoding of the observations to be used in subsequent code. *markin* is rarely used.

*svymarkout* sets the to-use variable to 0 wherever any of the survey-characteristic variables contain missing values; it is discussed in *[SVY] svymarkout* and is not further discussed here.

**Syntax**

*Create marker variable after syntax*

```stata
marksample lname [ , novarlist strok zeroweight noby ]
```

*Create marker variable*

```stata
mark newmarkvar [ if ] [ in ] [ weight ] [ , zeroweight noby ]
```

*Modify marker variable*

```stata
markout markvar [ varlist ] [ , strok sysmissok ]
```

*Find range containing selected observations*

```stata
markin [ if ] [ in ] [ , name(lcname) noby ]
```

*Modify marker variable based on survey-characteristic variables*

```stata
svymarkout markvar
```

*aweights, fweights, iweights, and pweights* are allowed; see *[U] 11.1.6 weight.* *varlist* may contain time-series operators; see *[U] 11.4.4 Time-series varlists.*
Options

`novarlist` is for use with `marksample`. It specifies that missing values among variables in `varlist` not cause the marker variable to be set to 0. Specify `novarlist` if you previously specified `syntax newvarlist ...`

or

`syntax newvarname ...`

You should also specify `novarlist` when missing values are not to cause observations to be excluded (perhaps you are analyzing the pattern of missing values).

`strok` is used with `marksample` or `markout`. Specify this option if string variables in `varlist` are to be allowed. `strok` changes rule 6 in `Remarks and examples` below to read “The marker variable is set to 0 in observations for which any of the string variables in `varlist` contain "".”

`zeroweight` is for use with `marksample` or `mark`. It deletes rule 1 in `Remarks and examples` below, meaning that observations will not be excluded because the weight is zero.

`noby` is used rarely and only in `byable(recall)` programs. It specifies that, in identifying the sample, the restriction to the by-group be ignored. `mark` and `marksample` are to create the marker variable as they would had the user not specified the by prefix. If the user did not specify the by prefix, specifying `noby` has no effect. `noby` provides a way for `byable(recall)` programs to identify the overall sample. For instance, if the program needed to calculate the percentage of observations in the by-group, the program would need to know both the sample to be used on this call and the overall sample. The program might be coded as

```
program ..., byable(recall)
  ...
  marksample touse
  marksample alluse, noby
  ...
  quietly count if `touse'
  local curN = r(N)
  quietly count if `alluse'
  local totN = r(N)
  local frac = `curN'/'totN'
  ...
end
```

See `[P] byable`.

`sysmissok` is used with `markout`. Specify this option if numeric variables in `varlist` equal to system missing (.) are to be allowed and only numeric variables equal to extended missing (., .a, .b, ...) are to be excluded. The default is that all missing values (., .a, .b, ...) are excluded.

`name(lclname)` is for use with `markin`. It specifies the name of the macro to be created. If `name()` is not specified, the name `in` is used.

Remarks and examples

`marksample`, `mark`, and `markout` are for use in Stata programs. They create a 0/1 variable recording which observations are to be used in subsequent code. The idea is to determine the relevant sample early in the code:
marksample, mark, and markout assist in this.

program ...
    (parse the arguments)
    (use mark* to create temporary variable ‘touse’ containing 0 or 1)
    rest of code ... if ‘touse’
end

marksample is for use in programs where the arguments are parsed using the syntax command; see [P] syntax. marksample creates a temporary byte variable, stores the name of the temporary variable in lmacname, and fills in the temporary variable with 0s and 1s according to whether the observation should be used. This determination is made by accessing information stored by syntax concerning the varlist, if exp, etc., allowed by the program. Its typical use is

program ...
    syntax ...
    marksample touse
    rest of code ... if ‘touse’
end

mark starts with an already created temporary variable name. It fills in newmarkvar with 0s and 1s according to whether the observation should be used according to the weight, if exp, and in range specified. markout modifies the variable created by mark by resetting it to contain 0 in observations that have missing values recorded for any of the variables in varlist. These commands are typically used as

program ...
    (parse the arguments)
    tempvar touse
    mark ‘touse’ ...
    markout ‘touse’ ...
    rest of code ... if ‘touse’
end

marksample is better than mark because there is less chance that you will forget to include some part of the sample restriction. markout can be used after mark or marksample when there are variables other than the varlist and when observations that contain missing values of those variables are also to be excluded. For instance, the following code is common:

program ...
    syntax ... [, Denom(varname) ... ]
    marksample touse
    markout ‘touse’ ‘denom’
    rest of code ... if ‘touse’
end

Regardless of whether you use mark or marksample, followed or not by markout, the following rules apply:

1. The marker variable is set to 0 in observations for which weight is 0 (but see the zeroweight option).
2. The appropriate error message is issued, and everything stops if weight is invalid (such as being less than 0 in some observation or being a noninteger for frequency weights).
3. The marker variable is set to 0 in observations for which if exp is not satisfied.
4. The marker variable is set to 0 in observations outside in range.
5. The marker variable is set to 0 in observations for which any of the numeric variables in varlist contain a numeric missing value.
6. The marker variable is set to 0 in all observations if any of the variables in varlist are strings; see the strok option for an exception.
7. The marker variable is set to 1 in the remaining observations.

Using the name touse is a convention, not a rule, but it is recommended for consistency between programs.

Technical note

markin is for use after marksample, mark, and markout and should be used only with extreme caution. Its use is never necessary, but when it is known that the specified if exp will select a small subset of the observations (small being, for example, 6 of 750,000), using markin can result in code that executes more quickly. markin creates local macro ‘lclname’ (or ‘in’ if name() is not specified) containing the smallest in range that contains the if exp.

By far the most common programming error—made by us at StataCorp and others—is to use different samples in different parts of a Stata program. We strongly recommend that programmers identify the sample at the outset. This is easy with marksample (or alternatively, mark and markout). Consider a Stata program that begins

```stata
program myprog
    version 15.0
    syntax varlist [if] [in]
    ...
end
```

Pretend that this program makes a statistical calculation based on the observations specified in varlist that do not contain missing values (such as a linear regression). The program must identify the observations that it will use. Moreover, because the user can specify if exp or in range, these restrictions must also be taken into account. marksample makes this easy:

```stata
version 15.0
syntax varlist [if] [in]
marksample touse
...
end
```

To produce the same result, we could create the temporary variable touse and then use mark and markout as follows:

```stata
program myprog
    version 15.0
    syntax varlist [if] [in]
    tempvar touse
    mark ‘touse’ ‘if’ ‘in’
    markout ‘touse’ ‘varlist’
    ...
end
```

The result will be the same.
The `mark` command creates temporary variable `touse` (temporary because of the preceding `tempvar`; see [P] `macro`) based on the `if exp` and `in range`. If there is no `if exp` or `in range`, `touse` will contain 1 for every observation in the data. If `if price>1000` was specified by the user, only observations for which `price` is greater than 1,000 will have `touse` set to 1; the remaining observations will have `touse` set to 0.

The `markout` command updates the `touse` marker created by `mark`. For observations where `touse` is 1—observations that might potentially be used—the variables in `varlist` are checked for missing values. If such an observation has any variables equal to missing, the observation’s `touse` value is reset to 0.

Thus observations to be used all have `touse` set to 1. Including `if `touse` at the end of statistical or data management commands will restrict the command to operate on the appropriate sample.

Example 1

Let’s write a program to do the same thing as `summarize`, except that our program will also engage in casewise deletion—if an observation has a missing value in any of the variables, it is to be excluded from all the calculations.

```bash
program cwsumm
version 15.0
syntax [varlist(fv ts)] [if] [in] [aweight fweight] [, Detail noFormat]
marksample touse
summarize `varlist' [weight=`exp'] if `touse', `detail' `format'
end
```

Technical note

Let’s now turn to `markin`, which is for use in those rare instances where you, as a programmer, know that only a few of the observations are going to be selected, that those small number of observations probably occur close together in terms of observation number, and that speed is important. That is, the use of `markin` is never required, and a certain caution is required in its use, so it is usually best to avoid it. On the other hand, when the requirements are met, `markin` can speed programs considerably.

The safe way to use `markin` is to first write the program without it and then splice in its use. Form a `touse` variable in the usual way by using `marksample`, `mark`, and `markout`. Once you have identified the `touse` sample, use `markin` to construct an `in range` from it. Then add `in` on every command in which `if `touse` appears, without removing the `if `touse`.

That is, pretend that our original code reads like the following:

```bash
program ...
syntax ...
marksample touse
mark `touse' ...
// touse now fully set
generate ... if `touse'
replace ... if `touse'
summarize ... if `touse'
replace ... if `touse'
...
end
```
We now change our code to read as follows:

```stata
program ...
syntax ...
marksample touse
mark 'touse' ... // touse now fully set
markin if 'touse' // <- new
    // we add 'in':
generate ... if 'touse' 'in'
replace ... if 'touse' 'in'
summarize ... if 'touse' 'in'
replace ... if 'touse' 'in'
...
end
```

This new version will, under certain conditions, run faster. Why? Consider the case when the program is called and there are 750,000 observations in memory. Let’s imagine that the 750,000 observations are a panel dataset containing 20 observations each on 37,500 individuals. Let’s further imagine that the dataset is sorted by `subjectid`, the individual identifier, and that the user calls our program and includes the restriction if `subject_id==4225`.

Thus our program must select 20 observations from the 750,000. That’s fine, but think about the work that `generate`, `replace`, `summarize`, and `replace` must each go to in our original program. Each must thumb through 750,000 observations, asking themselves whether `touse` is true, and 749,980 times, the answer is no. That will happen four times.

`markin` will save Stata work here. It creates a macro named `in` of the form “in $j_1/j_2$”, where $j_1$ to $j_2$ is the narrowest range that contains all the `touse` ≠ 0 values. Under the assumptions we made, that range will be exactly 20 long; perhaps it will be in 84500/84520. Now the `generate`, `replace`, `summarize`, and `replace` commands will each restrict themselves to those 20 observations. This will save them much work and the user much time.

Because there is a speed advantage, why not always use `markin` in our programs? Assume that between the `summarize` and the `replace` there was a `sort` command in our program. The in range constructed by `markin` would be inappropriate for our last `replace`; we would break our program.

If we use `markin`, we must make sure that the in range constructed continues to be valid throughout our program (our construct a new one when it changes). So that is the first answer: you cannot add `markin` without thinking. The second answer is that `markin` takes time to execute, albeit just a little, and that time is usually wasted because in range will not improve performance because the data are not ordered as required. Taking the two reasons together, adding `markin` to most programs is simply not worth the effort.

When it is worth the effort, you may wonder why, when we added `in` to the subsequent commands, we did not simultaneously remove if `touse`. The answer is that `in` is not a guaranteed substitute for if. In our example, under the assumptions made, the `in` happens to substitute perfectly, but that was just an assumption, and we have no guarantees that the user happens to have his or her data sorted in the desired way. If, in our program, we sorted the data, and then we used `markin` to produce the range, we could omit if `touse`, but even then, we do not recommend it. We always recommend programming defensively, and the cost of evaluating if `touse`, when `in` really does restrict the sample to the relevant observations, is barely measurable.

[U] 18 Programming Stata
markdown — Convert Markdown document to an HTML file

Description

markdown converts a Markdown document to an HTML file.

Syntax

markdown srcfile, saving(targetfile) [options]

*srcfile* is the Markdown document to be converted.
You may enclose *srcfile* and *targetfile* in double quotes and must do so if they contain blanks or special characters.

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>saving(targetfile)</em></td>
<td>specify the target file to be saved</td>
</tr>
<tr>
<td>replace</td>
<td>replace the target file if it already exists</td>
</tr>
<tr>
<td>hardwrap</td>
<td>replace hard wraps (actual line breaks) with the HTML tag <code>&lt;br&gt;</code></td>
</tr>
<tr>
<td>nomsg</td>
<td>suppress message of a link to targetfile</td>
</tr>
</tbody>
</table>

*saving(targetfile)* is required.

Options

*saving(targetfile)* specifies the target file to be saved. *saving()* is required.

replace specifies that the target file be replaced if it already exists.

hardwrap specifies that hard wraps (actual line breaks) in the Markdown document be replaced with the HTML line break tag `<br>`.

nomsg suppresses the message that contains a link to the target file.

Remarks and examples

markdown converts a Markdown document to an HTML file. A Markdown document is written using an easy-to-read, plain-text, lightweight markup language. For a detailed discussion and the syntax of markdown, see the Markdown Wikipedia page.

Stata uses Flexmark’s Pegdown emulation as its default Markdown document processing engine. For information on Pegdown’s flavor of Markdown, see the Pegdown GitHub page.

See [P] dyndoc and [P] dyntext for a full description of Stata’s dynamic document-generation commands. markdown is used by dyndoc but may also be used directly by programmers.

**Table**

matlist — Display a matrix and control its format

<table>
<thead>
<tr>
<th>Description</th>
<th>Syntax</th>
<th>Style options</th>
</tr>
</thead>
<tbody>
<tr>
<td>General options</td>
<td>Syntax for the second syntax</td>
<td>Remarks and examples</td>
</tr>
</tbody>
</table>

**Description**

matlist displays a matrix, allowing you to control the display format. Row and column names are used as the row and column headers. Equation names are displayed in a manner similar to estimation results.

Columns may have different formats, and lines may be shown between each column. You cannot format rows of the matrix differently.

matlist is an extension of the matrix list command (see [P] matrix utility).

**Syntax**

*One common display format for every column*

```
matlist matrix_exp [, style_options general_options ]
```

*Each column with its own display format*

```
matlist matrix_exp, cspec(cspec) rspec(rspec) [ general_options ]
```

**Style options**

</tbody>
</table>
bspec | Border lines are drawn ... 
--- | ---
none | no border lines are drawn; the default
all | around all four sides
rows | at the top and bottom
columns | at the left and right
left | at the left
right | at the right
top | at the top
bottom | at the bottom

general_options | Description
--- | ---
title(string) | title displayed above table
tindent(#) | indent title # spaces
rowtitle(string) | title to display above row names
names(rows) | display row names
names(columns) | display column names
names(all) | display row and column names; the default
names(none) | suppress row and column names
nonames | same as names(none)
showcoleq(ceq) | specify how column equation names are displayed
roweqonly | display only row equation names
coleqonly | display only column equation names
colorcoleq(txt|res) | display mode (color) for column equation names; default is txt
keepcoleq | keep columns of the same equation together
aligncolnames(ralign) | right-align column names
aligncolnames(lalign) | left-align column names
aligncolnames(center) | center column names
noblank | suppress blank line before tables
nohalf | display full matrix even if symmetric
nodotz | display missing value .z as blank
underscore | display underscores as blanks in row and column names
linesize(#) | overrule linesize setting

ceq | Equation names are displayed
--- | ---
first | over the first column only; the default
each | over each column
combined | centered over all associated columns
lcombined | left-aligned over all associated columns
rcombined | right-aligned over all associated columns
Style options

`lines(lstyle)` specifies where lines are drawn in the display of `matrix_exp`. The following values of `lstyle` are allowed:

- **oneline** draws lines separating the row and column headers from the numerical entries. This is the default if the `matrix_exp` has no equation names.
- **eq** draws horizontal and vertical lines between equations. This is the default if the `matrix_exp` has row or column equation names.
- **rowtotal** is the same as `oneline` and has a line separating the last row (the totals) from the rest.
- **coltotal** is the same as `oneline` and has a line separating the last column (the totals) from the rest.
- **rctotal** is the same as `oneline` and has lines separating the last row and column (the totals) from the rest.
- **rows** draws horizontal lines between all rows and one vertical line between the row-label column and the first column with numerical entries.
- **columns** draws vertical lines between all columns and one horizontal line between the headers and the first numeric row.
- **cells** draws horizontal and vertical lines between all rows and columns.
- **none** suppresses all horizontal and vertical lines.

`border([bspec])` specifies the type of border drawn around the table. `bspec` is any combination of the following values:

- **none** draws no outside border lines and is the default.
- **all** draws all four outside border lines.
- **rows** draws horizontal lines in the top and bottom margins.
- **columns** draws vertical lines in the left and right margins.
- **left** draws a line in the left margin.
- **right** draws a line in the right margin.
- **top** draws a line in the top margin.
- **bottom** draws a line in the bottom margin.

`border` without an argument is equivalent to `border(all)`, or, equivalently, `border(left right top bottom)`.

`format(%fmt)` specifies the format for displaying the individual elements of the matrix. The default is `format(%9.0g)`. See [U] 12.5 Formats: Controlling how data are displayed.

`twidth(#)` specifies the width of the row-label column (first column); the default is `twidth(12)`.

`left(#)` specifies that the table be indented `#` spaces; the default is `left(0)`. To indent the title, see the `tindent()` option.

`right(#)` specifies that the right margin of the table be `#` spaces in from the page margin. The default is `right(0)`. The right margin affects the number of columns that are displayed before wrapping.
General options

`title(string)` adds `string` as the title displayed before the matrix. `matlist` has no default title or header.

`tindent(#)` specifies the indentation for the title; the default is `tindent(0)`.

`rowtitle(string)` specifies that `string` be used as a column header for the row labels. This option is allowed only when both row and column labels are displayed.

`names(rows|columns|all|none)` specifies whether the row and column names are displayed; the default is `names(all)`, which displays both.

`nonames` suppresses row and column names and is a synonym for `names(none)`.

`showcoleq(ceq)` specifies how column equation names are displayed. The following `ceq` are allowed:
- `first` displays an equation name over the first column associated with that name; this is the default.
- `each` displays an equation name over each column.
- `combined` displays an equation name centered over all columns associated with that name.
- `lcombined` displays an equation name left-aligned over all columns associated with that name.
- `rcombined` displays an equation name right-aligned over all columns associated with that name.

If necessary, equation names are truncated to the width of the field in which the names are displayed. With `combined`, `lcombined`, and `rcombined`, the field comprises all columns and the associated separators for the equation.

`roweqonly` specifies that only row equation names be displayed in the output. This option may not be combined with `names(columns)`, `names(none)`, or `nonames`.

`coeleqonly` specifies that only column equation names be displayed in the output. This option may not be combined with `names(rows)`, `names(none)`, or `nonames`.

`colorcoleq(txt|res)` specifies the mode (color) used for the column equation names that appear in the first displayed row. Specifying `txt` (the default) displays the equation name in the same color used to display text. Specifying `res` displays the name in the same color used to display results.

`keepcoleq` specifies that columns of the same equation be kept together if possible.

`aligncolnames(ralign|lalign|center)` specifies the alignment for the column names. `ralign` indicates alignment to the right, `lalign` indicates alignment to the left, and `center` indicates centering. `aligncolnames(ralign)` is the default.

`noblank` suppresses printing a blank line before the matrix. This is useful in programs.

`nohalf` specifies that, even if the matrix is symmetric, the full matrix be printed. The default is to print only the lower triangle in such cases.

`nodotz` specifies that `.z` missing values be listed as a field of blanks rather than as `.z`; see [U] 12.2.1 Missing values.

`underscore` converts underscores to blanks in row and column names.

`linesize(#)` specifies the width of the page for formatting the table. Specifying a value of `linesize()` wider than your screen width can produce truly ugly output on the screen, but that output can nevertheless be useful if you are logging output and later plan to print the log on a wide printer.
Required options for the second syntax

cspec(cspec) specifies the formatting of the columns and the separators of the columns,
where cspec is \([\text{sep} \ [\text{qual}] \ %\#\#s] \ \text{sep} \ \text{nspec} \ [\ldots]\)
and where \(\text{sep}\) is \([o\#] \ &|l \ [o\#] \)

\(\text{qual}\) is

<table>
<thead>
<tr>
<th>(\text{qual})</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>standard font</td>
</tr>
<tr>
<td>b</td>
<td>boldface font</td>
</tr>
<tr>
<td>i</td>
<td>italic font</td>
</tr>
<tr>
<td>t</td>
<td>text mode</td>
</tr>
<tr>
<td>e</td>
<td>error mode</td>
</tr>
<tr>
<td>c</td>
<td>command mode</td>
</tr>
<tr>
<td>L</td>
<td>left-aligned</td>
</tr>
<tr>
<td>R</td>
<td>right-aligned</td>
</tr>
<tr>
<td>C</td>
<td>centered</td>
</tr>
<tr>
<td>w#</td>
<td>field width #</td>
</tr>
</tbody>
</table>

\(\text{nspec}\) is \([\text{qual}] \ \text{nfmt} \ \text{sep}\)

\(\text{nfmt}\) is \(%\#.\#\{f|g\}\)

The first (optional) part, \([\text{sep} \ [\text{qual}] \ %\#\#s]\), of cspec specifies the formatting for the column containing row names. It is required if the row names are part of the display; see the \texttt{names()} option. The number of nspecs should equal the number of columns of \texttt{matname}.

In a separator specification, \(\text{sep}, l\) specifies that a vertical line be drawn. \& specifies that no line be drawn. The number of spaces before and after the separator may be specified with \(o\#\); these default to one space, except that by default no spaces are included before the first column and after the last column.

Here are examples for a matrix with two columns (three columns when you count the column containing the row labels):

\[
\text{cspec}(& \ %16s & \ %9.2f & \ %7.4f &)
\]

specifies that the first column, containing row labels, be displayed using 16 characters; the second column, with format \(\%9.2f\); and the third column, with format \(\%7.4f\). No vertical lines are drawn. The number of spaces before and after the table is 0. Columns are separated with two spaces.

\[
\text{cspec}(&o2 \ %16s \ o2&o2 \ %9.2f \ o2&o2 \ %7.4f \ o2&)
\]

specifies more white space around the columns (two spaces everywhere, for a total of four spaces between columns).

\[
\text{cspec}(|\%16s|\%9.2f|\%7.4f|)
\]

displays the columns in the same way as the first example but draws vertical lines before and after each column.

\[
\text{cspec}(| \ b \ %16s \ | \ %9.2f \ & \ %7.4f \ |)
\]

specifies that vertical lines be drawn before and after all columns, except between the two columns with numeric entries. The first column is displayed in the boldface font.
rspec(rspec) specifies where horizontal lines be drawn. rspec consists of a sequence of characters, optionally separated by white space. - (or synonym |) specifies that a line be drawn. & indicates that no line be drawn. When matname has \( r \) rows, \( r + 2 \) characters are required if column headers are displayed, and \( r + 1 \) characters are required otherwise. The first character specifies whether a line is to be drawn before the first row of the table; the second, whether a line is to be drawn between the first and second row, etc.; and the last character, whether a line is to be drawn after the last row of the table.

You cannot add blank lines before or after the horizontal lines.

For example, in a table with column headers and three numeric rows,

\[
\text{rspec(||&|)} \quad \text{or equivalently} \quad \text{rspec(--&--)}
\]

specifies that horizontal lines be drawn before the first and second rows and after the last row, but not elsewhere.

Remarks and examples

Remarks are presented under the following headings:

- All columns with the same format
- Different formats for each column
- Other output options

All columns with the same format

The matrix list command displays Stata matrices but gives you little control over formatting; see \([P] \text{matrix utility}\).

The matlist command, on the other hand, offers a wide array of options to give you more detailed control over the formatting of the output.

The output produced by matlist is a rectangular table of numbers with an optional row and column on top and to the left of the table. We distinguish two cases. In the first style, all numeric columns are to be displayed in the same format. In the second style, each column and each intercolumn divider is formatted individually.
We demonstrate with a simple $3 \times 2$ matrix, $A$.

```
. matrix A = ( 1,2 \ 3,4 \ 5,6 )
. matrix list A
A[3,2]
c1  c2
r1  1  2
r2  3  4
r3  5  6
```

Like `matrix list`, the `matlist` command displays one matrix but adopts a tabular display style.

```
. matlist A
   c1   c2
   r1   1   2
   r2   3   4
   r3   5   6
```

Other border lines at the left, top, right, and bottom of the table may be specified with the `border()` option. For instance, `border(rows)` specifies a horizontal line at the top and bottom margins. `rowtitle()` specifies a row title. To make it easier to organize output with multiple matrices, you can use the `left()` option to left-indent the output.

```
. matlist A, border(rows) rowtitle(rows) left(4)
   rows  c1   c2
   r1    1   2
   r2    3   4
   r3    5   6
```

The `lines()` option specifies where internal lines are to be drawn. `lines(none)` suppresses all internal horizontal and vertical lines. `lines(all)` displays lines between all rows and columns. `twidth()` specifies the width of the first column—the column containing the row names. By default, `matlist` shows row and column names obtained from the matrix resulting from `matrix_exp`. `names(rows)` specifies that the row names be shown, and the column names be suppressed. `names(none)` would suppress all row and column names. You may also display a title for the table, displayed in SMCL paragraph mode; see `[P] smcl`. If the table is indented, the title will be shown with a hanging indent. The `tindent()` option allows you to indent the title as well. Finally, `matlist` allows a matrix expression—convenient for interactive use. Enclose the matrix expression in parentheses if the expression itself contains commas.

```
. matlist 2*A, border(all) lines(none) format(%6.1f) names(rows) twidth(8) > left(4) title(Guess what, a title)
```

```
   Guess what, a title
   r1  2.0  4.0
   r2  6.0  8.0
   r3 10.0 12.0
```
Example 2

By default, `matlist` draws vertical and horizontal lines between equations.

```stata
. matrix E = ( 1 , 2 , 3 , 4 , 5 , 6 , 7 \
   > 8 , 9 , 10 , 11 , 12 , 13 , 14 \
   > 15 , 16 , 17 , 18 , 19 , 20 , 21 \
   > 22 , 23 , 24 , 25 , 26 , 27 , 28 \
   > 29 , 30 , 31 , 32 , 33 , 34 , 35 \
   > 36 , 37 , 38 , 39 , 40 , 41 , 42 )
. matrix colnames E = A:a1 A:a2 B:b1 B:b2 C:c1 C:c2 C:c3
. matrix rownames E = D:d1 D:d2 E:e1 E:e2 F:f1 F:f2
. matlist E
```

`matlist` wraps the columns, if necessary. The `keepcoleq` option keeps all columns of an equation together. By default, `matlist` shows the equation name left-aligned over the first column associated with the equation. Equation names are truncated, if necessary. We may also display equation names in the field created by combining the columns associated with the equation. In this wider field, truncation of equation names will be rare. The `showcoleq(combined)` option displays the equation names centered in this combined field. See the description of the `showcoleq()` option for other ways to format the column equation names. The `border(right)` displays a vertical line to the right of the table. If the table is wrapped, a border line is shown to the right of each panel.
Different formats for each column

matlist allows you to format each column’s display format (for example, %8.2f for the data columns), type style (for example, boldface font), and alignment. You may also specify whether a vertical line is to be drawn between the columns and the number of spaces before and after the line.

Example 3

We illustrate the different formatting options with the example of a matrix of test results, one row per test, with the last row representing an overall test.

```
. matrix Htest = ( 12.30, 2, .00044642 \
                   2.17, 1, .35332874 \
                   8.81, 3, .04022625 \
                   20.05, 6, .00106763 )
. matrix rownames Htest = trunk length weight overall
. matrix colnames Htest = chi2 df p
```
Again we can display the matrix Htest with matrix list,

```
. matrix list Htest
Htest[4,3]          chi2     df     p
        trunk  12.3     2   0.00044642
        length  2.17     1   0.35332874
        weight  8.81     3   0.04022625
      overall  20.05     6   0.00106763
```

or with matlist,

```
. matlist Htest
                      chi2     df     p
        trunk   12.3     2   0.0004464
        length   2.17     1   0.3533287
        weight   8.81     3   0.0402262
      overall  20.05     6   0.0010676
```

Neither of these displays of Htest is attractive because all columns are the same width and the numbers are formatted with the same display format. matlist can provide a better display of the matrix Htest.

```
. matlist Htest, rowtitle(Variables) title(Test results)
> cspec(o4& %12s | %8.0g & %5.0f & %8.4f o2&) rspec(&-&&--)
```

Test results

<table>
<thead>
<tr>
<th>Variables</th>

<th>df</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>trunk</td>
<td>12.3</td>
<td>2</td>
<td>0.0004464</td>
</tr>
<tr>
<td>length</td>
<td>2.17</td>
<td>1</td>
<td>0.3533287</td>
</tr>
<tr>
<td>weight</td>
<td>8.81</td>
<td>3</td>
<td>0.0402262</td>
</tr>
<tr>
<td>overall</td>
<td>20.05</td>
<td>6</td>
<td>0.0010676</td>
</tr>
</tbody>
</table>

The cspec() and rspec() options may look somewhat intimidating at first, but they become clear if we examine their parts. The table for matrix Htest has four columns: one string column with the row names and three numeric columns with chi2 statistics, degrees of freedom, and p-values. There are also five separators: one before the first column, three between the columns, and one after the last column. Thus the cspec() specification is made up of $4 + 5 = 9$ elements that are explained in the next table.

<table>
<thead>
<tr>
<th>Element</th>
<th>Purpose</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o4k</td>
<td>before column 1</td>
<td>4 spaces/no vertical line</td>
</tr>
<tr>
<td>%12s</td>
<td>display format column 1</td>
<td>string display format %12s</td>
</tr>
<tr>
<td></td>
<td>between columns 1 and 2</td>
<td>1 space/vertical line/1 space</td>
</tr>
<tr>
<td>%8.0g</td>
<td>display format column 2</td>
<td>numeric display format %8.0g</td>
</tr>
<tr>
<td>&amp;</td>
<td>between columns 2 and 3</td>
<td>1 space/no vertical line/1 space</td>
</tr>
<tr>
<td>%5.0f</td>
<td>display format column 3</td>
<td>numeric display format %5.0f</td>
</tr>
<tr>
<td>&amp;</td>
<td>between columns 3 and 4</td>
<td>1 space/no vertical line/1 space</td>
</tr>
<tr>
<td>%8.4f</td>
<td>display format column 4</td>
<td>numeric display format %8.4f</td>
</tr>
<tr>
<td>o2k</td>
<td>after column 4</td>
<td>2 spaces/no vertical line</td>
</tr>
</tbody>
</table>

Vertical lines are drawn if the separator consists of a \| character, whereas no vertical line is drawn with an \& specification. By default, one space is displayed before and after the vertical line;
the exception is that, by default, no space is displayed before the first separator and after the last separator. More white space may be added by adding o specifications. For instance, o3 | o2, or more compactly o3|o2, specifies that three spaces be included before the vertical line and two spaces after the line.

The rspec() row formatting specification for a table with r rows (including the column headers) comprises a series of r + 1 − and & characters, where

− denotes that a horizontal line is to be drawn and
& denotes that no horizontal line is to be drawn.

The table for matrix Htest has five rows: the column headers and four data rows. The specification rspec(&−&−−) is detailed in the next table.

<table>
<thead>
<tr>
<th>Element</th>
<th>Purpose</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>before row 1</td>
<td>no line is drawn</td>
</tr>
<tr>
<td>−</td>
<td>between rows 1 and 2</td>
<td>a line is drawn</td>
</tr>
<tr>
<td>&amp;</td>
<td>between rows 2 and 3</td>
<td>no line is drawn</td>
</tr>
<tr>
<td>&amp;</td>
<td>between rows 3 and 4</td>
<td>no line is drawn</td>
</tr>
<tr>
<td>−</td>
<td>between rows 4 and 5</td>
<td>a line is drawn</td>
</tr>
<tr>
<td>−</td>
<td>after row 5</td>
<td>a line is drawn</td>
</tr>
</tbody>
</table>

Lines are drawn before and after the last row of the table for matrix Htest to emphasize that this row is an overall (total) test.

Further formatting is possible. For instance, we can specify that the second column (the first numeric column) be in the boldface font and text mode and that the last column be in italic and command mode. We simply insert appropriate qualifiers in the specification part for the respective columns.

.matlist Htest, rowt(Variables) title(Test results (again))
> cspec( o4&o2 %10s | b t %8.0g & %4.0f & i c %7.4f o2& )
> rspec( & − & & − & )

Test results (again)

<table>
<thead>
<tr>

<td>2.17</td>
<td>1</td>
<td>0.3533</td>
</tr>
<tr>
<td>weight</td>
<td>8.81</td>
<td>3</td>
<td>0.0402</td>
</tr>
<tr>
<td>overall</td>
<td>20.05</td>
<td>6</td>
<td>0.0011</td>
</tr>
</tbody>
</table>

In this manual, the boldface font is used for the chi2 column and the italic font is used for the p column, but there is no difference due to the requested text mode and command mode. If we run this example interactively, both the font change and color change due to the requested mode can be seen depending on your Results window color scheme. Depending on your settings, the chi2 column might display in the boldface font and the green color (text mode); the df column, in the default standard font and the yellow color (result mode); and the p column, in the italic font and the white color (command mode). Or it may look exactly as it does in this manual.
Other output options

Example 4

Finally, we illustrate two options for use with the extended missing value \texttt{.z} and with row and column names that contain underscores.

```
. matrix Z = (.z, 1 \ .c, .z )
. matrix rownames Z = row_1 row_2
. matrix colnames Z = col1 col2
. matlist Z

<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col2</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_1</td>
<td>.z</td>
<td>1</td>
</tr>
<tr>
<td>row_2</td>
<td>.c</td>
<td>.z</td>
</tr>
</tbody>
</table>
```

The \texttt{nodotz} option displays \texttt{.z} as blanks. Underscores in row names are translated into spaces with the \texttt{underscore} option.

```
. matlist Z, nodotz underscore

<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col2</th>
</tr>
</thead>
<tbody>
<tr>
<td>row 1</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>row 2</td>
<td>.c</td>
<td></td>
</tr>
</tbody>
</table>
```

[U] 14 Matrix expressions
Description

An introduction to matrices in Stata is found in [U] 14 Matrix expressions. This entry provides an overview of the {cmd:matrix} commands and provides more background information on matrices in Stata.

Beyond the {cmd:matrix} commands, Stata has a complete matrix programming language, Mata, that provides more advanced matrix functions, support for complex matrices, fast execution speed, and the ability to directly access Stata’s data, macros, matrices, and returned results. Mata can be used interactively as a matrix calculator, but it is even more useful for programming; see the Mata Reference Manual.

Remarks and examples

Remarks are presented under the following headings:

- Overview of matrix commands
- Creating and replacing matrices
- Namespace
- Naming conventions in programs

Overview of matrix commands

Documentation on matrices in Stata is grouped below into three categories—Basics, Programming, and Specialized. We recommend that you begin with [U] 14 Matrix expressions and then read [P] matrix define. After that, feel free to skip around.

Basics

- [U] 14 Matrix expressions: Introduction to matrices in Stata
- [P] matrix define: Matrix definition, operators, and functions
- [P] matrix utility: List, rename, and drop matrices
- [P] matlist: Display a matrix and control its format

Programming

- [P] matrix accum: Form cross-product matrices
- [R] ml: Maximum likelihood estimation
- [P] ereturn: Post the estimation results
- [P] matrix rownames: Name rows and columns
- [P] matrix score: Score data from coefficient vectors

Specialized

- [P] makecns: Constrained estimation
- [P] matrix mkmat: Convert variables to matrix and vice versa
- [P] matrix svd: Singular value decomposition
- [P] matrix symeigen: Eigenvalues and eigenvectors of symmetric matrices
- [P] matrix eigenvalues: Eigenvalues of nonsymmetric matrices
- [P] matrix get: Access system matrices
- [P] matrix dissimilarity: Compute similarity or dissimilarity measures

338
Creating and replacing matrices

Matrices generally do not have to be preallocated or dimensioned before creation, except when you want to create an \( r \times c \) matrix and then fill in each element one by one; see the description of the \texttt{J()} function in \cite{matrix define}. Matrices are typically created by \texttt{matrix define} or \texttt{matrix accum}; see \cite{matrix accum}.

Stata takes a high-handed approach to redefining matrices. You know that, when dealing with data, you must distinguish between creating a new variable or replacing the contents of an existing variable—Stata has two commands for this: \texttt{generate} and \texttt{replace}. For matrices, there is no such distinction. If you define a new matrix, it is created. If you give the same command and the matrix already exists, then the currently existing matrix is destroyed and the new one is defined. This treatment is the same as that given to macros and scalars.

Namespace

The term “namespace” refers to how names are interpreted. For instance, the variables in your dataset occupy one namespace—other things, such as value labels, macros, and scalars, can have the same name and not cause confusion.

Macros also have their own namespace; macros can have the same names as other things, and Stata can still tell by context when you are referring to a macro because of the punctuation. When you type \texttt{gen newvar=myname, myname} must refer to a variable. When you type \texttt{gen newvar=’myname’}—note the single quotes around \texttt{myname}—\texttt{myname} must refer to a local macro. When you type \texttt{gen newvar=$myname}, \texttt{myname} must refer to a global macro.

Scalars and matrices share the same namespace; that is, scalars and matrices may have the same names as variables in the dataset, etc., but they cannot have the same names as each other. Thus when you define a matrix called, say, \texttt{myres}, if a scalar by that name already exists, it is destroyed, and the matrix replaces it. Correspondingly, when you define a scalar called \texttt{myres}, if a matrix by that name exists, it is destroyed, and the scalar replaces it.

Naming conventions in programs

If you are writing Stata programs or ado-files using matrices, you may have some matrices that you wish to leave behind for other programs to build upon, but you will certainly have other matrices that are nothing more than leftovers from calculations. Such matrices are called \textit{temporary}. You should use Stata’s \texttt{tempname} facility (see \cite{macro}) to name such matrices. These matrices will automatically be discarded when your program ends. For example, a piece of your program might read

\begin{verbatim}
    tempname YXX XX
    matrix accum ‘YXX’ = price weight mpg
    matrix ‘XX’ = ‘YXX’[2...,2...]
\end{verbatim}

Note the single quotes around the names after they are obtained from \texttt{tempname}; see \cite{18.3 Macros}.

Technical note

Let’s consider writing a regression program in Stata. (There is actually no need for such a program because Stata already has the \texttt{regress} command.) A well-written estimation command would allow the \texttt{level()} option for specifying the width of confidence intervals, and it would replay results when the command is typed without arguments. Here is a well-written version:

\begin{verbatim}
    tempname YXX XX
    matrix accum ‘YXX’ = price weight mpg
    matrix ‘XX’ = ‘YXX’[2...,2...]
\end{verbatim}
The syntax of our new command is

```
myreg depvar indepvars [if] [in] [ , level(#) ]
```

myreg, typed without arguments, redisplays the output of the last myreg command. After estimation with myreg, the user may use correlate to display the covariance matrix of the estimators, predict to obtain predicted values or standard errors of the prediction, and test to test linear hypotheses about the estimated coefficients. The command is indistinguishable from any other Stata estimation command.

Despite the excellence of our work, we do have some criticisms:

- **myreg** does not display the ANOVA table, $R^2$, etc.; it should and could be made to, although we would have to insert our own display statements before the `ereturn display` instruction.

- The program makes copious use of matrices with different names, resulting in extra memory use while the estimation is being made; the code could be made more economical, if less readable, by reusing matrices.

- **myreg** makes the least-squares calculation by using the absolute cross-product matrix, an invitation to numerical problems if the data are not consistently scaled. Stata’s own `regress` command is more careful, and we could be, too: `matrix accum` does have an option for forming the cross-product matrix in deviation form, but its use would complicate this program. This does not overly concern us, although we should make a note of it when we document myreg. Nowadays, users...
expect to be protected in linear regression but have no such expectations for more complicated estimation schemes because avoiding the problem can be difficult.

There is one nice feature of our program that did not occur to us when we wrote it. We use `invsym()` to form the inverse of the cross-product matrix, and `invsym()` can handle singular matrices. If there is a collinearity problem, `myreg` behaves just like `regress`: it omits the offending variables and notes that they are omitted when it displays the output (at the `ereturn display` step).

Technical note

Our linear regression program is longer than we might have written in an exclusively matrix programming language. After all, the coefficients can be obtained from $(X'X)^{-1}X'y$, and in a dedicated matrix language, we would type nearly that, and obtaining the standard errors would require only a few more matrix calculations. In fact, we did type nearly that to make the calculation; the extra lines in our program have to do mostly with syntax issues and linking to the rest of Stata. In writing your own programs, you might be tempted not to bother linking to the rest of Stata. Fight this temptation.

Linking to the rest of Stata pays off: here we do not merely display the numerical results, but we display them in a readable form, complete with variable names. We made a command that is indistinguishable from Stata’s other estimation commands. If the user wants to test $b[\text{denver}]=b[\text{la}]$, the user types literally that; there is no need to remember the matrix equation and to count variables (such as constrain the third minus the 15th variable to sum to zero).

*Mata Reference Manual*
matrix accum — Form cross-product matrices

Description

matrix accum accumulates cross-product matrices from the data to form $A = X'X$.

matrix glsaccum accumulates cross-product matrices from the data by using a specified inner weight matrix to form $A = X'BX$, where $B$ is a block diagonal matrix.

matrix opaccum accumulates cross-product matrices from the data by using an inner weight matrix formed from the outer product of a variable in the data to form

$$A = X'_1e'_1X_1 + X'_2e'_2X_2 + \cdots + X'_K e'_K X_K$$

where $X_i$ is a matrix of observations from the $i$th group of the `varlist` variables and $e_i$ is a vector formed from the observations in the $i$th group of the `opvar` variable.

matrix vecaccum accumulates the first variable against the remaining variables in `varlist` to form a row vector of accumulated inner products to form $a = x'_1X$, where $X = (x_2, x_3, \ldots)$.

Also see [M-5] `cross()` for other routines for forming cross-product matrices.

Syntax

Accumulate cross-product matrices to form $X'X$

```
matrix accum A = varlist [if] [in] [weight] [ , noconstant deviations means(m) absorb(varname)]
```

Accumulate cross-product matrices to form $X'BX$

```
matrix glsaccum A = varlist [if] [in] [weight] , group(groupvar)
glsmat(W | stringvar) row(rowvar) [noconstant]
```

Accumulate cross-product matrices to form $\sum X'_i e'_i X_i$

```
matrix opaccum A = varlist [if] [in] , group(groupvar)
opvar(opvar) [noconstant]
```

Accumulate first variable against remaining variables

```
matrix vecaccum a = varlist [if] [in] [weight] [ , noconstant]
```

`varlist` in `matrix accum` and in `matrix vecaccum` may contain factor variables (except for the first variable in `matrix vecaccum varlist`); see [U] 11.4.3 Factor variables.

`varlist` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.
Options

noconstant suppresses the addition of a “constant” to the $X$ matrix. If noconstant is not specified, it is as if a column of 1s is added to $X$ before the accumulation begins. For instance, for matrix accum without noconstant, $X^\prime X$ is really $(X, 1)'(X, 1)$, resulting in

\[
\begin{pmatrix}
X'X & X'1 \\
1'X & 1'1
\end{pmatrix}
\]

Thus the last row and column contain the sums of the columns of $X$, and the element in the last row and column contains the number of observations. If $p$ variables are specified in varlist, the resulting matrix is $(p + 1) \times (p + 1)$. Specifying noconstant suppresses the addition of this row and column (or just the column for matrix vecaccum).

deviations, allowed only with matrix accum, causes the accumulation to be performed in terms of deviations from the mean. If noconstant is not specified, the accumulation of $X$ is done in terms of deviations, but the added row and column of sums are not in deviation format (in which case they would be zeros). With noconstant specified, the resulting matrix, divided through by $N - 1$, where $N$ is the number of observations, is a covariance matrix.

means($m$), allowed only with matrix accum, creates matrix $m$: $1 \times (p + 1)$ or $1 \times p$ (depending on whether noconstant is also specified) containing the means of $X$.

absorb($varname$), allowed only with matrix accum, specifies that matrix accum compute the accumulations in terms of deviations from the mean within the absorption groups identified by $varname$.

group($groupvar$) is required with matrix glsaccum and matrix opaccum and is not allowed otherwise. In the two cases where it is required, it specifies the name of a variable that identifies groups of observations. The data must be sorted by $groupvar$.

In matrix glsaccum, $groupvar$ identifies the observations to be individually weighted by glsmat().

In matrix opaccum, $groupvar$ identifies the observations to be weighted by the outer product of opvar().

glsmat($W$|$stringvar$), required with matrix glsaccum and not allowed otherwise, specifies the name of the matrix or the name of a string variable in the dataset that contains the name of the matrix that is to be used to weight the observations in group(). $stringvar$ must be str8 or less.

row($rowvar$), required with matrix glsaccum and not allowed otherwise, specifies the name of a numeric variable containing the row numbers that specify the row and column of the glsmat() matrix to use in the inner-product calculation.

opvar($opvar$), required with matrix opaccum, specifies the variable used to form the vector whose outer product forms the weighting matrix.

Remarks and examples

Remarks are presented under the following headings:

- matrix accum
- matrix glsaccum
- matrix opaccum
- matrix vecaccum
- Treatment of user-specified weights
matrix accum

matrix accum is a straightforward command that accumulates one matrix that holds $X'X$ and $X'y$, which is typically used in $b = (X'X)^{-1}X'y$. Say that we wish to run a regression of the variable price on mpg and weight. We can begin by accumulating the full cross-product matrix for all three variables:

\[
\begin{align*}
\text{. use http://www.stata-press.com/data/r15/auto} \\
\text{(1978 Automobile Data)} \\
\text{. matrix accum A = price weight mpg} \\
\text{(obs=74)} \\
\text{. matrix list A} \\
\end{align*}
\]

\[
\begin{array}{cccc}
\text{symmetric A[4,4]} & \\
\text{price} & \text{weight} & \text{mpg} & \text{_cons} \\
\text{price} & 3.448e+09 & \text{} & \text{} \\
\text{weight} & 1.468e+09 & 7.188e+08 & \text{} \\
\text{mpg} & 9132716 & 4493720 & 36008 \\
\text{_cons} & 456229 & 223440 & 1576 & 74
\end{array}
\]

In our accumulation, matrix accum automatically added a constant; we specified three variables and got back a $4 \times 4$ matrix. The constant term is always added last. In terms of our regression model, the matrix we just accumulated has $y = \text{price}$ and $X = (\text{weight}, \text{mpg}, \_\text{cons})$ and can be written as

\[
A = (y,X)'(y,X) = \begin{pmatrix} y'y & y'X \\ X'y & X'X \end{pmatrix}
\]

Thus we can extract $X'X$ from the submatrix of $A$ beginning at the second row and column, and we can extract $X'y$ from the first column of $A$, omitting the first row:

\[
\begin{align*}
\text{. matrix XX = A[2...,2...]} \\
\text{. matrix list XX} \\
\text{symmetric XX[3,3]} \\
\text{weight} & \text{mpg} & \text{_cons} \\
\text{weight} & 7.188e+08 & \text{} & \text{} \\
\text{mpg} & 4493720 & 36008 & \text{} \\
\text{_cons} & 223440 & 1576 & 74 \\
\text{. matrix Xy = A[2...,1]} \\
\text{. matrix list Xy} \\
\text{Xy[3,1]} & \\
\text{price} & \text{} & \text{} \\
\text{weight} & 1.468e+09 & \text{} & \text{} \\
\text{mpg} & 9132716 & \text{} & \text{} \\
\text{_cons} & 456229 & \text{} & \text{}
\end{align*}
\]

We can now calculate $b = (X'X)^{-1}X'y$:

\[
\begin{align*}
\text{. matrix b = syminv(XX)*Xy} \\
\text{. matrix list b} \\
\text{b[3,1]} & \\
\text{price} & \text{} & \text{} \\
\text{weight} & 1.7465592 & \text{} & \text{} \\
\text{mpg} & -49.512221 & \text{} & \text{} \\
\text{_cons} & 1946.0687 & \text{} & \text{}
\end{align*}
\]

The same result could have been obtained directly from $A$:

\[
\begin{align*}
\text{. matrix b = invsym(A[2...,2...])*A[2...,1]}
\end{align*}
\]
Technical note

`matrix accum`, with the deviations and noconstant options, can also be used to obtain covariance matrices. The covariance between variables $x_i$ and $x_j$ is defined as

$$C_{ij} = \frac{\sum_{k=1}^{n}(x_{ik} - \bar{x}_i)(x_{jk} - \bar{x}_j)}{n - 1}$$

Without the deviations option, `matrix accum` calculates a matrix with elements

$$R_{ij} = \sum_{k=1}^{n}x_{ik}x_{jk}$$

and with the deviations option,

$$A_{ij} = \sum_{k=1}^{n}(x_{ik} - \bar{x}_i)(x_{jk} - \bar{x}_j)$$

Thus the covariance matrix $C = A/(n - 1)$.

```
. matrix accum Cov = price weight mpg, deviations noconstant
    (obs=74)
. matrix Cov = Cov/(r(N)-1)
. matrix list Cov
```

```
symmetric Cov[3,3]
    price  weight  mpg
    price  8699526
    weight 1234674.8  604029.84
    mpg   -7996.2829  -3629.4261  33.472047
```

In addition to calculating the cross-product matrix, `matrix accum` records the number of observations in `r(N)`, a feature we use in calculating the normalizing factor. With the `corr()` matrix function defined in [P] `matrix define`, we can convert the covariance matrix into a correlation matrix:

```
. matrix P = corr(Cov)
. matrix list P
```

```
symmetric P[3,3]

`matrix glsaccum`

`matrix glsaccum` is a generalization of `matrix accum` useful in producing GLS-style weighted accumulations. Whereas `matrix accum` produces matrices of the form $X'X$, `matrix glsaccum` produces matrices of the form $X'BX$, where

$$B = \begin{pmatrix}
    W_1 & 0 & \ldots & 0 \\
    0 & W_2 & \ldots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    0 & 0 & \ldots & W_K
\end{pmatrix}$$
The matrices $W_k$, $k = 1, \ldots, K$ are called the weighting matrices for observation group $k$. In the matrices above, each of the $W_k$ matrices is square, but there is no assumption that they all have the same dimension. By writing

$$X = \begin{pmatrix} X_1 \\ X_2 \\ \vdots \\ X_K \end{pmatrix}$$

the accumulation made by matrix glsaccum can be written as

$$X'BX = X'_1W_1X_1 + X'_2W_2X_2 + \cdots + X'_KW_KX_K$$

matrix glsaccum requires you to specify three options: \texttt{group(groupvar)}, \texttt{glsmat(stringvar)} or \texttt{glsmat(matvar)}, and \texttt{row(rowvar)}. Observations sharing the same value of \texttt{groupvar} are said to be in the same observation group—this specifies the group, $k$, in which they are to be accumulated. Before calling matrix glsaccum, you must sort the data by \texttt{groupvar}. How $W_k$ is assembled is the subject of the other two options.

Think of there being a superweighting matrix for the group, which we will call $V_k$. $V_k$ is specified by \texttt{glsmat()}. The same supermatrix can be used for all observations by specifying a \texttt{matname} as the argument to \texttt{glsmat()}, or, if a variable name is specified, different supermatrices can be specified—the contents of the variable will be used to obtain the particular name of the supermatrix. (More correctly, the contents of the variable for the first observation in the group will be used: supermatrices can vary across groups but must be the same within group.)

Weighting matrix $W_k$ is made from supermatrix $V_k$ by selecting the rows and columns specified in \texttt{row(rowvar)}. In the simple case, $W_k = V_k$. This happens when there are $m$ observations in the group and the first observation in the group has $rowvar = 1$, the second has $rowvar = 2$, and so on. To fix ideas, let $m = 3$ and write

$$V_1 = \begin{pmatrix} v_{11} & v_{12} & v_{13} \\ v_{21} & v_{22} & v_{23} \\ v_{31} & v_{32} & v_{33} \end{pmatrix}$$

$V$ need not be symmetric. Let’s pretend that the first 4 observations in our dataset contain

<table>
<thead>
<tr>
<th>obs. no.</th>
<th>groupvar</th>
<th>rowvar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>…</td>
</tr>
</tbody>
</table>

In these data, the first 3 observations are in the first group because they share an equal \texttt{groupvar}. It is not important that \texttt{groupvar} happens to equal 1; it is important that the values are equal. The \texttt{rowvars} are, in order, 1, 2, and 3, so $W_1$ is formed by selecting the first row and column of $V_1$, then the second row and column of $V_1$, and finally the third row and column of $V_1$: 

$$W_1 = \begin{pmatrix} v_{11} & v_{12} & v_{13} \\ v_{21} & v_{22} & v_{23} \\ v_{31} & v_{32} & v_{33} \end{pmatrix}$$
or \( W_1 = V_1 \). Now consider the same data, but reordered:

<table>
<thead>
<tr>
<th>obs. no.</th>
<th>groupvar</th>
<th>rowvar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>...</td>
</tr>
</tbody>
</table>

\( W_1 \) is now formed by selecting the second row and column, then the first row and column, and finally the third row and column of \( V_1 \). These steps can be performed sequentially, reordering first the rows and then the columns; the result is

\[
W_1 = \begin{pmatrix}
    v_{22} & v_{21} & v_{23} \\
    v_{12} & v_{11} & v_{13} \\
    v_{32} & v_{31} & v_{33}
\end{pmatrix}
\]

This reorganization of the \( W_1 \) matrix exactly undoes the reorganization of the \( X_1 \) matrix, so \( X'_1 W_1 X_1 \) remains unchanged. Given how \( W_k \) is assembled from \( V_k \), the order of the row numbers in the data does not matter.

**matrix glsaccum** is willing to carry this concept even further. Consider the following data:

<table>
<thead>
<tr>
<th>obs. no.</th>
<th>groupvar</th>
<th>rowvar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>...</td>
</tr>
</tbody>
</table>

Now \( rowvar \) equals 1 followed by 3 twice, so the first row and column of \( V_1 \) are selected, followed by the third row and column twice; the second column is never selected. The resulting weighting matrix is

\[
W_1 = \begin{pmatrix}
    v_{11} & v_{13} & v_{13} \\
    v_{31} & v_{33} & v_{33} \\
    v_{31} & v_{33} & v_{33}
\end{pmatrix}
\]

Such odd weighting would not occur in, say, time-series analysis, where the matrix might be weighting lags and leads. It could well occur in an analysis of individuals in families, where 1 might indicate the head of household, 2 a spouse, and 3 a child. In fact, such a case could be handled with a \( 3 \times 3 \) superweighting matrix \( V \), even if the family became large: the appropriate weighting matrix \( W_k \) would be assembled, on a group-by-group (family-by-family) basis, from the underlying supermatrix.

**matrix opaccum**

**matrix opaccum** is a special case of **matrix glsaccum**. **matrix glsaccum** calculates results of the form

\[
A = X'_1 W_1 X_1 + X'_2 W_2 X_2 + \cdots + X'_K W_K X_K
\]

Often \( W_i \) is simply the outer product of another variable in the dataset; that is,

\[
W_i = e_i e_i'
\]
where \( \mathbf{e}_i \) is the \( n_i \times 1 \) vector formed from the \( n_i \) \text{groupvar()} \) observations of the variable specified in \text{opvar()} \). The data must be sorted by \text{groupvar}.

**Example 1**

Suppose that we have a panel dataset that contains five variables: \( \text{id} \), \( t \), \( \mathbf{e} \) (a residual), and covariates \( \mathbf{x}_1 \) and \( \mathbf{x}_2 \). Further suppose that we need to compute

\[
\mathbf{A} = \mathbf{X}_1' \mathbf{e}_1 \mathbf{X}_1 + \mathbf{X}_2' \mathbf{e}_2 \mathbf{X}_2 + \cdots + \mathbf{X}_K' \mathbf{e}_K \mathbf{X}_K
\]

where \( \mathbf{X}_i \) contains the observations on \( \mathbf{x}_1 \) and \( \mathbf{x}_2 \) when \( \text{id}=i \) and \( \mathbf{e}_i \) contains the observations on \( \mathbf{e} \) when \( \text{id}=i \).

Below is the output from \text{xtdescribe} for our example data. There are 11 groups and the number of observations per group is not constant.

```
. use http://www.stata-press.com/data/r15/maccumxmpl
. xtdescribe, patterns(11)

  id: 1, 2, ..., 11  n = 11
  t: 1, 2, ..., 15  T = 15
  Delta(t) = 1 unit
  Span(t) = 15 periods
  (id*t uniquely identifies each observation)

  Distribution of T_i:  min  5%  25%  50%  75%  95%  max
                      5   5   7  10  13  15  15

  Freq.  Percent  Cum.  Pattern
    1      9.09     9.09  111111111111
    1      9.09    18.18  1111111111111
    1      9.09    27.27  11111111111111
    1      9.09    36.36  111111111111111
    1      9.09    45.45  1111111111111111
    1      9.09    54.55  11111111111111111
    1      9.09    63.64  111111111111111111
    1      9.09    72.73  1111111111111111111
    1      9.09    81.82  1111111111111111111
    1      9.09    90.91  1111111111111111111
    1      9.09    99.99  1111111111111111111
     1     100.00  11111111111111111111
```

If we were to calculate \( \mathbf{A} \) with \text{matrix glsaccum}, we would need to form 11 matrices and store their names in a string variable before calling \text{matrix glsaccum}. This step slows down \text{matrix glsaccum} when there are many groups. Also all the information contained in the \( \mathbf{W}_i \) matrices is contained in the variable \( \mathbf{e} \). It is this structure that \text{matrix opaccum} exploits to make a faster command for this type of problem:

```
. sort id t
. matrix opaccum A2 = x1 x2, group(id) opvar(e)
```
matrix vecaccum

The first variable in varlist is treated differently from the others by matrix vecaccum. Think of the first variable as specifying vector y and the remaining variables as specifying matrix X. matrix vecaccum makes the accumulation \( y'X \) to return a row vector with elements

\[
a_i = \sum_{k=1}^{n} y_k x_{ki}
\]

Like matrix accum, matrix vecaccum adds a constant, _cons, to X unless noconstant is specified.

matrix vecaccum serves two purposes. First, terms like \( y'X \) often occur in calculating derivatives of likelihood functions; matrix vecaccum provides a fast way of calculating them. Second, it is useful in time-series accumulations of the form

\[
C = \sum_{t=1}^{T} \sum_{k=\delta}^{T-k} x_{t-k} W_\delta r_{t-k} r_t
\]

In this calculation, X is an observation matrix with elements \( x_{tj} \), with \( t \) indexing time (observations) and \( j \) variables, \( t = 1, \ldots, T \) and \( j = 1, \ldots, p \). \( x_t \) \((1 \times p)\) refers to the \( t \)th row of this matrix. Thus \( C \) is a \( p \times p \) matrix.

The Newey–West covariance matrix uses the definition \( W_\delta = 1 - |\delta|/(k+1) \) for \( \delta \leq k \). To make the calculation, the user (programmer) cycles through each of the \( j \) variables, forming

\[
z_{tj} = \sum_{\delta=-k}^{k} x_{(t-\delta)j} W_\delta r_{t-\delta} r_t
\]

Writing \( z_j = (z_{1j}, z_{2j}, \ldots, z_{Tj})' \), we can then say that \( C \) is

\[
C = \sum_{j=1}^{p} z_j' X
\]

In this derivation, the user must decide in advance the maximum lag length, \( k \), such that observations that are far apart in time must have increasingly small covariances to establish the convergence results.

The Newey–West estimator is in the class of generalized method-of-moments (GMM) estimators. The choice of a maximum lag length, \( k \), is a reflection of the length in time beyond which the autocorrelation becomes negligible for estimating the variance matrix. The code fragment given below is merely for illustration of the matrix commands, because Stata includes estimation with the Newey–West covariance matrix in the newey command. See [TS] newey or Greene (2018, 999) for details on this estimator.

Calculations like \( z_j' X \) are made by matrix vecaccum, and \( z_j \) can be treated as a temporary variable in the dataset.

```
assume '1', '2', etc., contain the xs including constant
assume 'r' contains the r variable
assume 'k' contains the k range
tempname C factor t c
tempvar z
local p : word count '*'
matrix 'C' = J('p','p',0)
genenerate double 'z' = 0
forvalues d = 0/'k' {
    /* Add each submatrix twice except for
       the lag=0 case */
    scalar 'factor' = cond('d'>0, 1, .5)
```
local w = (1 - 'd' / ('k' + 1))
capture mat drop 't'
forvalues j = 1/’p’ {
    replace ‘z’ = ‘j’[_n-‘d’]*’w’*‘r’[_n-‘d’]*‘r’
    mat vecaccum ‘c’ = ‘z’ ‘*’, nocons
    mat ‘t’ = ‘t’ \ ‘c’
}
mat ‘C’ = ‘C’ + (‘t’ + ‘t’’) * ‘factor’
local ‘p’ = "_cons" // Rename last var to _cons
mat rownames ‘C’ = ‘*’
mat colnames ‘C’ = ‘*’
assume inverse and scaling for standard-error reports

Treatment of user-specified weights

matrix accum, matrix glsaccum, and matrix vecaccum all allow weights. Here is how they are treated:

All three commands can be thought of as returning something of the form $X_1' B X_2$. matrix accum, $X_1 = X_2$ and $B = I$; for matrix glsaccum, $X_1 = X_2$; and matrix vecaccum, $B = I$, $X_1$ is a column vector and $X_2$ is a matrix.

The commands really calculate $X_1' W^{1/2} B W^{1/2} X_2$, where $W$ is a diagonal matrix. If no weights are specified, $W = I$. Now assume that weights are specified, and let $v: 1 \times n$ be the specified weights. If fweights or pweights are specified, $W = \text{diag}(v)$. If aweights are specified, $W = \text{diag}(v/(1'v)(1'1))$, meaning that the weights are normalized to sum to the number of observations. If iweights are specified, they are treated like fweights, except that the elements of $v$ are not restricted to be positive integers.

Stored results

matrix accum, matrix glsaccum, matrix opaccum, and matrix vecaccum store the number of observations in r(N). matrix accum stores the number of absorption groups in r(k_absorb). matrix glsaccum (with aweights) and matrix vecaccum also store the sum of the weight in r(sum_w), but matrix accum does not.

**Description**

`matrix define` performs matrix computations. The word `define` may be omitted.

`matrix input` provides a method for inputting matrices. The word `input` may be omitted (see the discussion that follows).

For an introduction and overview of matrices in Stata, see [U] 14 Matrix expressions. See [M-2] exp for matrix expressions in Mata.

**Menu**

- **matrix define**
  Data > Matrices, ado language > Define matrix from expression

- **matrix input**
  Data > Matrices, ado language > Input matrix by hand

**Syntax**

*Perform matrix computations*

```
matrix [define] matname = matrix_expression
```

*Input matrices*

```
matrix [input] matname = (# [,# ...] [\ # [, # ...] [\ [ ... ] ]])
```

**Remarks and examples**

Remarks are presented under the following headings:

- Introduction
- Inputting matrices by hand
- Matrix operators
- Matrix functions returning matrices
- Matrix functions returning scalars
- Subscripting and element-by-element definition
- Name conflicts in expressions (namespaces)
- Macro extended functions
Introduction

`matrix define` calculates matrix results from other matrices. For instance,

```
.matrix define D = A + B + C
```

creates `D` containing the sum of `A`, `B`, and `C`. The word `define` may be omitted,

```
.matrix D = A + B + C
```

and the command may be further abbreviated:

```
.mat D=A+B+C
```

The same matrix may appear on both the left and the right of the equal sign in all contexts, and Stata will not become confused. Complicated matrix expressions are allowed.

With `matrix input`, you define the matrix elements rowwise; commas are used to separate elements within a row, and backslashes are used to separate the rows. Spacing does not matter.

```
.matrix input A = (1,2\3,4)
```

The above would also work if you omitted the `input` subcommand.

```
.matrix A = (1,2\3,4)
```

There is a subtle difference: the first method uses the `matrix input` command, and the second uses the matrix expression parser. Omitting `input` allows expressions in the command. For instance,

```
.matrix X = (1+1, 2*3/4 \ 5/2, 3)
```

is understood but

```
.matrix input X = (1+1, 2*3/4 \ 5/2, 3)
```

would produce an error.

`matrix input`, however, has two advantages. First, it allows input of large matrices. (The expression parser is limited because it must “compile” the expressions and, if the result is too long, will produce an error.) Second, `matrix input` allows you to omit the commas.

Inputting matrices by hand

Before turning to operations on matrices, let’s examine how matrices are created. Typically, at least in programming situations, you obtain matrices by accessing one of Stata’s internal matrices (`e(b)` and `e(V)`; see [P] matrix get) or by accumulating it from the data (see [P] matrix accum). Nevertheless, the easiest way to create a matrix is to enter it using `matrix input`—this may not be the normal way to create matrices, but it is useful for performing small, experimental calculations.

Example 1

To create the matrix

\[
A = \begin{pmatrix}
1 & 2 \\
3 & 4
\end{pmatrix}
\]

type

```
.matrix A = (1,2 \ 3,4)
```
The spacing does not matter. To define the matrix

\[ B = \begin{pmatrix} 1 & 2 & 3 \\ 4 & . & 6 \end{pmatrix} \]

type

`. matrix B = (1,2,3 \ 4,.,6)`

To define the matrix

\[ C = \begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \end{pmatrix} \]

type

`. matrix C = (1,2 \ 3,4 \ 5,6)`

If you need more than one line, and you are working interactively, just keep typing; Stata will wrap the line around the screen. If you are working in a do- or ado-file, see \[U\] \[16.1.3 Long lines in do-files\].

To create vectors, you enter the elements, separating them by commas or backslashes. To create the row vector

\[ D = (1 \ 2 \ 3) \]

type

`. matrix D = (1,2,3)`

To create the column vector

\[ E = \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \]

type

`. matrix E = (1\2\3)`

To create the 1 \times 1 matrix \[ F = (2) \], type

`. matrix F = (2)`

In these examples, we have omitted the \texttt{input} subcommand. They would work either way.

\section*{Matrix operators}

In what follows, uppercase letters \( A, B, \ldots \) stand for matrix names. The matrix operators are:

\texttt{+}, meaning addition. \texttt{matrix C=A+B, A:} \( r \times c \) and \texttt{B:} \( r \times c \), creates \texttt{C:} \( r \times c \) containing the elementwise addition \( A + B \). An error is issued if the matrices are not conformable. Row and column names are obtained from \texttt{B}.

\texttt{-}, meaning subtraction or negation. \texttt{matrix C=A-B, A:} \( r \times c \) and \texttt{B:} \( r \times c \), creates \texttt{C} containing the elementwise subtraction \( A - B \). An error is issued if the matrices are not conformable. \texttt{matrix C=-A} creates \texttt{C} containing the elementwise negation of \texttt{A}. Row and column names are obtained from \texttt{B}. 

*, meaning multiplication. matrix C=A*B, A: a × b and B: b × c, returns C: a × c containing the matrix product AB; an error is issued if A and B are not conformable. The row names of C are obtained from the row names of A, and the column names of C from the column names of B.

matrix C=A*s or matrix C=s*A, A: a × b and s a Stata scalar (see [P] scalar) or a literal number, returns C: a × b containing the elements of A each multiplied by s. The row and column names of C are obtained from A. For example, matrix VC=MYMAT*2.5 multiplies each element of MYMAT by 2.5 and stores the result in VC.

/, meaning matrix division by scalar. matrix C=A/s, A: a × b and s a Stata scalar (see [P] scalar) or a literal number, returns C: a × b containing the elements of A each divided by s. The row and column names of C are obtained from A.

#, meaning the Kronecker product. matrix C=A#B, A: a × b and B: c × d, returns C: ac × bd containing the Kronecker product A ⊗ B, all elementwise products of A and B. The upper-left submatrix of C is the product A_1,1B; the submatrix to the right is A_1,2B; and so on. Row and column names are obtained by using the subnames of A as resulting equation names and the subnames of B for the subnames of C in each submatrix.

Nothing, meaning copy. matrix B=A copies A into B. The row and column names of B are obtained from A. The matrix rename command (see [P] matrix utility) will rename instead of copy a matrix.

', meaning transpose. matrix B=A', A: r × c, creates B: c × r containing the transpose of A. The row names of B are obtained from the column names of A and the column names of B from the row names of A.

\, meaning join columns by row. matrix C=A,B, A: a × b and B: a × c, returns C: a × (b + c) containing A in columns 1 through b and B in columns b + 1 through b + c (the columns of B are appended to the columns of A). An error is issued if the matrices are not conformable. The row names of C are obtained from A. The column names are obtained from A and B.

\, meaning join rows by column. matrix C=A\B, A: a × b and B: c × b, returns C: (a + c) × b containing A in rows 1 through a and B in rows a + 1 through a + c (the rows of B are appended to the rows of A). An error is issued if the matrices are not conformable. The column names of C are obtained from A. The row names are obtained from A and B.

matrix define allows complicated matrix expressions. Parentheses may be used to control the order of evaluation. The default order of precedence for the matrix operators (from highest to lowest) is

<table>

Technical note

Programmers: Watch out for confusion when combining ‘’, meaning to transpose with local macros, where ‘’ is one of the characters that enclose macro names: ‘mname’. Stata will not become confused, but you might. Compare:

. matrix ’new1’ = ’old’
     and
. matrix ’new2’ = ’old’

Matrix ’new2’ contains matrix ’old’, transposed. Stata will become confused if you type

. matrix ’C’ = ’A’’B’

because the backslash in front of the ‘B’ makes the macro processor take the left quote literally. No substitution is ever made for ‘B’. Even worse, the macro processor assumes that the backslash was meant for it and so removes the character! Pretend that ‘A’ contained a, ‘B’ contained b, and ‘C’ contained c. After substitution, the line would read

. matrix c = a’b’

which is not at all what was intended. To make your meaning clear, put a space after the backslash,

. matrix ’C’ = ’A’ ’B’

which would then be expanded to read

. matrix c = a \ b

Matrix functions returning matrices

In addition to matrix operators, Stata has matrix functions, which allow expressions to be passed as arguments. The following matrix functions are provided:

matrix A=I(dim) defines A as the $dim \times dim$ identity matrix, where dim is a scalar expression and will be rounded to the nearest integer. For example, matrix A=I(3) defines A as the $3 \times 3$ identity matrix.
matrix \( \mathbf{A} = \mathbf{J}(r,c,z) \) defines \( \mathbf{A} \) as an \( r \times c \) matrix containing elements \( z \), \( r \), \( c \), and \( z \) are scalar expressions with \( r \) and \( c \) rounded to the nearest integer. For example, matrix \( \mathbf{A} = \mathbf{J}(2,3,0) \) returns a \( 2 \times 3 \) matrix containing 0 for each element.

matrix \( \mathbf{L} = \text{cholesky}(\mathbf{mexp}) \) performs Cholesky decomposition. An error is issued if the matrix expression \( \mathbf{mexp} \) does not evaluate to a square, symmetric matrix. For example, matrix \( \mathbf{L} = \text{cholesky}(\mathbf{A}) \) produces the lower triangular (square root) matrix \( \mathbf{L} \), such that \( \mathbf{L} \mathbf{L}' = \mathbf{A} \). The row and column names of \( \mathbf{L} \) are obtained from \( \mathbf{A} \).

matrix \( \mathbf{B} = \text{inv}(\mathbf{mexp}) \), if \( \mathbf{mexp} \) evaluates to a square but not necessarily symmetric or positive-definite matrix, returns the inverse. A singular matrix will result in an error. The row names of \( \mathbf{B} \) are obtained from the column names of \( \mathbf{mexp} \), and the column names of \( \mathbf{B} \) are obtained from the row names of \( \mathbf{mexp} \).

matrix \( \mathbf{B} = \text{sweep}(\mathbf{mexp}, n) \) applies the sweep operator to the \( n \)th row and column of the square matrix resulting from the matrix expression \( \mathbf{mexp} \). \( n \) is a scalar expression and will be rounded to the nearest integer. The names of \( \mathbf{B} \) are obtained from \( \mathbf{mexp} \), except that the \( n \)th row and column names are interchanged. For \( \mathbf{A} \): \( n \times n \), \( \mathbf{B} = \text{sweep}(\mathbf{A}, k) \) produces \( \mathbf{B} \): \( n \times n \), defined as

\[
B_{kk} = \frac{1}{A_{kk}}
\]

\[
B_{ik} = -\frac{A_{ik}}{A_{kk}}, \quad i \neq k \quad \text{(kth column)}
\]

\[
B_{kj} = \frac{A_{ij}}{A_{kk}}, \quad j \neq k \quad \text{(jth row)}
\]

\[
B_{ij} = A_{ij} - \frac{A_{ik}A_{kj}}{A_{kk}}, \quad i \neq k, j \neq k
\]

matrix \( \mathbf{B} = \text{corr}(\mathbf{mexp}) \), where \( \mathbf{mexp} \) evaluates to a covariance matrix, stores the corresponding correlation matrix in \( \mathbf{B} \). The row and column names are obtained from \( \mathbf{mexp} \).

matrix \( \mathbf{B} = \text{diag}(\mathbf{mexp}) \), where \( \mathbf{mexp} \) evaluates to a row or column vector (\( 1 \times c \) or \( c \times 1 \)), creates \( \mathbf{B} \): \( c \times c \) with diagonal elements from \( \mathbf{mexp} \) and off-diagonal elements 0. The row and column names are obtained from the column names of \( \mathbf{mexp} \) if \( \mathbf{mexp} \) is a row vector or the row names if \( \mathbf{mexp} \) is a column vector.

matrix \( \mathbf{B} = \text{vec}(\mathbf{mexp}) \), where \( \mathbf{mexp} \) evaluates to an \( r \times c \) matrix, creates \( \mathbf{B} \): \( rc \times 1 \) containing the elements of \( \mathbf{mexp} \) starting with the first column and proceeding column by column.

matrix \( \mathbf{B} = \text{vecdiag}(\mathbf{mexp}) \), where \( \mathbf{mexp} \) evaluates to a square \( c \times c \) matrix, creates \( \mathbf{B} \): \( 1 \times c \) containing the diagonal elements from \( \mathbf{mexp} \). \text{vecdiag()} is the opposite of \text{diag()}. The row name is set to \( r1 \). The column names are obtained from the column names of \( \mathbf{mexp} \).

matrix \( \mathbf{B} = \text{matuniform}(r,c) \) creates \( \mathbf{B} \): \( r \times c \) containing uniformly distributed pseudorandom numbers on the interval \([0,1]\).

matrix \( \mathbf{B} = \text{hadamard}(\mathbf{mexp}, \mathbf{nexp}) \), where \( \mathbf{mexp} \) and \( \mathbf{nexp} \) evaluate to \( r \times c \) matrices, creates a matrix whose \((i,j)\) element is \( \mathbf{mexp}[i,j] \cdot \mathbf{nexp}[i,j] \). If \( \mathbf{mexp} \) and \( \mathbf{nexp} \) do not evaluate to matrices of the same size, this function reports a conformability error.
nullmat(B) may only be used with the row-join (,) and column-join (\) operators, and informs Stata that B might not exist. If B does not exist, the row-join or column-join operator simply returns the other matrix-operator argument. An example of the use of nullmat() is given in [FN] Matrix functions.

matrix B = get(systemname) returns in B a copy of the Stata internal matrix systemname; see [P] matrix get. You can obtain the coefficient vector and variance–covariance matrix after an estimation command either with matrix get or by reference to e(b) and e(V).

Example 3

The examples are, once again, artificial but informative.

Matrix functions returning scalars

In addition to the above functions used with `matrix define`, which can be described as matrix functions returning matrices, there are matrix functions that return mathematical scalars. The list of functions that follow should be viewed as a continuation of [U] 13.3 Functions. If the functions listed below are used in a scalar context (for example, used with `display` or `generate`), then `A`, `B`, ... below stand for matrix names (possibly as a string literal or string variable name—details later). If the functions below are used in a matrix context (in `matrix define` for instance), then `A`, `B`, ... may also stand for matrix expressions.

`rowsof(A)` and `colsof(A)` return the number of rows or columns of `A`.

`rownumb(A,string)` and `colnumb(A,string)` return the row or column number associated with the name specified by `string`. For instance, `rownumb(MYMAT,"price")` returns the row number (say, 3) in `MYMAT` that has the name `price` (substring `price` and equation name blank). `colnumb(MYMAT,"out2:price")` returns the column number associated with the name `out2:price` (substring `price` and equation name `out2`). If row or column name is not found, missing is returned.

`rownumb()` and `colnumb()` can also return the first row or column number associated with an equation name. For example, `colnumb(MYMAT,"out2:")` returns the first column number in `MYMAT` that has equation name `out2`. Missing is returned if the equation name `out2` is not found.

`trace(A)` returns the sum of the diagonal elements of square matrix `A`. If `A` is not square, missing is returned.

`det(A)` returns the determinant of square matrix `A`. The determinant is the volume of the \((p-1)\)-dimensional manifold described by the matrix in \(p\)-dimensional space. If `A` is not square, missing is returned.

`diag0cnt(A)` returns the number of zeros on the diagonal of the square matrix `A`. If `A` is not square, missing is returned.

`issymmetric(A)` returns 1 if the matrix is symmetric and 0 otherwise.

`matmissing(A)` returns 1 if any elements of the matrix are missing and 0 otherwise.

`mreldif(A,B)` returns the relative difference of matrix `A` and `B`. If `A` and `B` do not have the same dimensions, missing is returned. The matrix relative difference is defined as

\[
\max_{i,j} \left( \frac{|A[i,j] - B[i,j]|}{|B[i,j]| + 1} \right)
\]

`el(A,i,j)` and `A[i,j]` return the \((i,j)\) element of `A`. Usually either construct may be used; `el(MYMAT,2,3)` and `MYMAT[2,3]` are equivalent, although `MYMAT[2,3]` is more readable. For the second construct, however, `A` must be a matrix name—it cannot be a string literal or string
variable. The first construct allows \texttt{A} to be a matrix name, string literal, or string variable. For instance, assume that \texttt{mymat} (as opposed to \texttt{MYMAT}) is a string variable in the dataset containing matrix names. \texttt{mymat[2,3]} refers to the (2,3) element of the matrix named \texttt{mymat}, a matrix that probably does not exist, and so produces an error. \texttt{el(mymat,2,3)} refers to the data variable \texttt{mymat}; the contents of that variable will be taken to obtain the matrix name, and \texttt{el()} will then return the (2,3) element of that matrix. If that matrix does not exist, Stata will not issue an error; because you referred to it indirectly, the \texttt{el()} function will return missing.

In either construct, \texttt{i} and \texttt{j} may be any expression (an \texttt{exp}) evaluating to a real. \texttt{MYMAT[2,3+1]} returns the (2,4) element. In programs that loop, you might refer to \texttt{MYMAT[‘i’, ‘j’+1]}.

In a matrix context (such as \texttt{matrix define}), the first argument of \texttt{el()} may be a matrix expression. For instance, \texttt{matrix A = B*el(B-C,1,1)} is allowed, but \texttt{display el(B-C,1,1)} would be an error because \texttt{display} is in a scalar context.

The matrix functions returning scalars defined above can be used in any context that allows an expression—what is abbreviated \texttt{exp} in the syntax diagrams throughout this manual. For instance, \texttt{trace()} returns the (scalar) trace of a matrix. Say that you have a matrix called \texttt{MYX}. You could type

\begin{verbatim}
. generate tr = trace(MYX)
\end{verbatim}

although this would be a silly thing to do. It would force Stata to evaluate the trace of the matrix many times, once for each observation in the data, and it would then store that same result over and over again in the new data variable \texttt{tr}. But you could do it because, if you examine the syntax diagram for \texttt{generate} (see \texttt{[D] generate}), \texttt{generate} allows an \texttt{exp}.

If you just wanted to see the trace of \texttt{MYX}, you could type

\begin{verbatim}
. display trace(MYX)
\end{verbatim}

because the syntax diagram for \texttt{display} also allows an \texttt{exp}; see \texttt{[P] display}. You could do either of the following:

\begin{verbatim}
. local tr = trace(MYX)
. scalar tr = trace(MYX)
\end{verbatim}

This is more useful because it will evaluate the trace only once and then store the result. In the first case, the result will be stored in a local macro (see \texttt{[P] macro}); in the second, it will be stored in a Stata scalar (see \texttt{[P] scalar}).

\section*{Example 4}

Storing the number as a scalar is better for two reasons: it is more accurate (scalars are stored in double precision), and it is faster (macros are stored as printable characters, and this conversion is a time-consuming operation). Not too much should be made of the accuracy issue; macros are stored with at least 13 digits, but it can sometimes make a difference.

In any case, let’s demonstrate that both methods work by using the simple trace function:

\begin{verbatim}
. matrix A = (1,6\8,4)
. local tr = trace(A)
. display ‘tr’ 5
. scalar sctr = trace(A)
. scalar list sctr
  sctr = 5
\end{verbatim}
Subscripting and element-by-element definition

matrix B = A[r_1, r_2], for range expressions \( r_1 \) and \( r_2 \) (defined below), extracts a submatrix from \( A \) and stores it in \( B \). Row and column names of \( B \) are obtained from the extracted rows and columns of \( A \). In what follows, assume that \( A \) is \( a \times b \).

A range expression can be a literal number. For example, matrix \( B = A[1,2] \) would return a \( 1 \times 1 \) matrix containing \( A_{1,2} \).

A range expression can be a number followed by two periods followed by another number, meaning the rows or columns from the first number to the second. For example, matrix \( B = A[2..4,1..5] \) would return a \( 3 \times 5 \) matrix containing the second through fourth rows and the first through fifth columns of \( A \).

A range expression can be a number followed by three periods, meaning all the remaining rows or columns from that number. For example, matrix \( B = A[3,4...] \) would return a \( 1 \times b - 3 \) matrix (row vector) containing the fourth through last elements of the third row of \( A \).

A range expression can be a quoted string, in which case it refers to the row or column with the specified name. For example, matrix \( B = A["price","mpg"] \) returns a \( 1 \times 1 \) matrix containing the element whose row name is price and column name is mpg, which would be the same as matrix \( B = A[2,3] \) if the second row were named price and the third column mpg. matrix \( B = A["price",1...] \) would return the \( 1 \times b \) vector corresponding to the row named price. In either case, if there is no matrix row or column with the specified name, an error is issued, and the return code is set to 111. If the row or column names include both an equation name and a subname, the fully qualified name must be specified, as in matrix \( B = A["eq1:price",1...] \).

A range expression can be a quoted string containing only an equation name, in which case it refers to all rows or columns with the specified equation name. For example, matrix \( B = A["eq1:","eq1:" ] \) would return the submatrix of rows and columns that have equation names eq1.

A range expression containing a quoted string referring to an element (not to an entire equation) can be combined with the .. and ... syntaxes above: For example, matrix \( B = A["price"...,"price"...] \) would define \( B \) as the submatrix of \( A \) beginning with the rows and columns corresponding to price. matrix \( B = A["price"...,"mpg","price"...,"mpg"] \) would define \( B \) as the submatrix of \( A \) starting at rows and columns corresponding to price and continuing through the rows and columns corresponding to mpg.

A range expression can be mixed. For example, matrix \( B = A[1.."price",2] \) defines \( B \) as the column vector extracted from the second column of \( A \) containing the first element through the element corresponding to price.

Scalar expressions may be used in place of literal numbers. The resulting number will be rounded to the nearest integer. Subscripting with scalar expressions may be used in any expression context (such as generate or replace). Subscripting with row and column names may be used only in a matrix expression context. This is really not a constraint; see the \( \text{rownumb() and colnumb()} \) functions discussed previously in the section titled Matrix functions returning scalars.

matrix \( A[r,c] = \text{exp} \) changes the \( r,c \) element of \( A \) to contain the result of the evaluated scalar expression, as defined in [U] 13 Functions and expressions, and as further defined in Matrix functions returning scalars. \( r \) and \( c \) may be scalar expressions and will be rounded to the nearest integer. The matrix \( A \) must already exist; the matrix function \( \text{J()} \) can be used to achieve this.

matrix \( A[r,c] = \text{mexp} \) places the matrix resulting from the \( \text{mexp} \) matrix expression into the already existing matrix \( A \), with the upper-left corner of the \( \text{mexp} \) matrix located at the \( r,c \) element of \( A \). If there is not enough room to place the \( \text{mexp} \) matrix at that location, a conformability error will
be issued, and the return code will be set to 503. \( r \) and \( c \) may be scalar expressions and will be rounded to the nearest integer.

\[ \text{Example 5} \]

Continuing with our artificial but informative examples,

```plaintext
. matrix A = (1,2,3,4\5,6,7,8\9,10,11,12\13,14,15,16)

. matrix rownames A = eq1:alpha eq1:beta eq2:alpha eq2:beta
. matrix colnames A = eq1:one eq1:two eq2:one eq2:two
```
Technical note

matrix \( A[i,j] = \text{exp} \) can be used to implement matrix formulas that perhaps Stata does not have built in. Let’s pretend that Stata could not multiply matrices. We could still multiply matrices, and after some work, we could do so conveniently. Given two matrices, \( A: a \times b \) and \( B: b \times c \), the \((i,j)\) element of \( C = AB \), \( C: a \times c \), is defined as

\[
C_{ij} = \sum_{k=1}^{b} A_{ik}B_{kj}
\]
Here is a Stata program to make that calculation:

```stata
program matmult
version 15.0
args A B C
if colsof(A)!=rowsof(B) { // check conformability
    error 503
}
local a = rowsof(A) // obtain dimensioning information
local b = colsof(A)
local c = colsof(B) // scalars above
matrix `C' = J(`a','c',0) // create result containing 0s
forvalues i = 1/`a' {
    forvalues j = 1/`c' {
        forvalues k = 1/`b' {
            matrix `C'[`i',`j'] = `C'[`i',`j'] + /*
* 'A'[`i',`k']*`B'[`k',`j']
        }
    }
}
end
```

Now if in some other program, we needed to multiply matrix \( XXI \) by \( Xy \) to form result \( \beta \), we could type `matmult XXI Xy beta` and never use Stata’s built-in method for multiplying matrices (`matrix beta=XXI*Xy`). If we typed the program `matmult` into a file named `matmult.ado`, we would not even have to bother to load `matmult` before using it—it would be loaded automatically; see \([U] 17 \text{ Ado-files}\).

### Name conflicts in expressions (namespaces)

See \([P] \text{ matrix}\) for a description of namespaces. A matrix might have the same name as a variable in the dataset, and if it does, Stata might appear confused when evaluating an expression (an `exp`). When the names conflict, Stata uses the rule that it always takes the data-variable interpretation. You can override this.

First, when working interactively, you can avoid the problem by simply naming your matrices differently from your variables.

Second, when writing programs, you can avoid name conflicts by obtaining names for matrices from `tempname`; see \([P] \text{ macro}\).

Third, whether working interactively or writing programs, when using names that might conflict, you can use the `matrix()` pseudofunction to force Stata to take the matrix-name interpretation.

`matrix(name)` says that `name` is to be interpreted as a matrix name. For instance, consider the statement `local new=trace(xx)`. This might work and it might not. If `xx` is a matrix and there is no variable named `xx` in your dataset, it will work. If there is also a numeric variable named `xx` in your dataset, it will not work. Typing the statement will produce a type-mismatch error—Stata assumes that when you type `xx`, you are referring to the data variable `xx` because there is a data variable `xx`. Typing `local new=trace(matrix(xx))` will then produce the desired result. When writing programs using matrix names not obtained from `tempname`, you are strongly advised to state explicitly that all matrix names are indeed matrix names by using the `matrix()` function.

The only exception to this recommendation has to do with the construct `A[i,j]`. The two subscripts indicate to Stata that `A` must be a matrix name and not an attempt to subscript a variable, so `matrix()` is not needed. This exception applies only to `A[i,j]`; it does not apply to `el(A,i,j)`, which would be more safely written as `el(matrix(A),i,j)`.
The matrix() and scalar() pseudofunctions (see [P] scalar) are really the same function, but you do not need to understand this fine point to program Stata successfully. Understanding this might, however, lead to producing more readable code. The formal definition is this:

`scalar(exp)` (and therefore `matrix(exp)`) evaluates `exp` but restricts Stata to interpreting all names in `exp` as scalar or matrix names. Scalars and matrices share the same namespace.

Therefore, because `scalar()` and `matrix()` are the same function, typing `trace(matrix(xx))` or `trace(scalar(xx))` would do the same thing, even though the second looks wrong. Because `scalar()` and `matrix()` allow an `exp`, you could also type `scalar(trace(xx))` and achieve the same result. `scalar()` evaluates the `exp` inside the parentheses: it merely restricts how names are interpreted, so now `trace(xx)` clearly means the trace of the matrix named `xx`.

How can you make your code more readable? Pretend that you wanted to calculate the trace plus the determinant of matrix `xx` and store it in the Stata scalar named `tpd` (no, there is no reason you would ever want to make such a silly calculation). You are writing a program and want to protect yourself from `xx` also existing in the dataset. One solution would be

```
scalar tpd = trace(matrix(xx)) + det(matrix(xx))
```

Knowing the full interpretation rule, however, you realize that you can shorten this to

```
scalar tpd = matrix(trace(xx) + det(xx))
```

and then, to make it more readable, you substitute `scalar()` for `matrix()`:

```
scalar tpd = scalar(trace(xx) + det(xx))
```

Macro extended functions

The following macro extended functions (see [P] macro) are also defined:

- `rownames A` and `colnames A` return a list of all the row or column subnames (with time-series operators if applicable) of `A`, separated by single blanks. The equation names, even if present, are not included.
- `roweq A` and `coleq A` return a list of all the row equation names or column equation names of `A`, separated by single blanks, and with each name appearing however many times it appears in the matrix.

- `rowfullnames A` and `colfullnames A` return a list of all the row or column names, including equation names of `A`, separated by single blanks.

Example 6

These functions are provided as macro functions and standard expression functions because Stata’s expression evaluator works only with strings of no more than 2,045 characters, something not true of Stata’s macro parser. A matrix with many rows or columns can produce an exceedingly long list of names.
In sophisticated programming situations, you sometimes want to process the matrices by row and column names rather than by row and column numbers. Assume that you are programming and have two matrices, \(xx\) and \(yy\). You know that they contain the same column names, but they might be in a different order. You want to reorganize \(yy\) to be in the same order as \(xx\). The following code fragment will create ‘newyy’ (a matrix name obtained from `tempname`) containing \(yy\) in the same order as \(xx\):

```stata
// Code fragment to reorganize \(yy\) to match \(xx\)

tempname newyy newcol
local names : colfullnames(xx)
foreach name of local names {
    local j = colnumb(yy,"'name'")
    if 'j'>=. {
        display as error "column for 'name' not found"
        exit 111
    }
    matrix 'newcol' = yy[1..., 'j']
    matrix 'newyy' = nullmat('newyy'), 'newcol'
}
```

*Mata Reference Manual*
**Description**

`matrix dissimilarity` computes a similarity, dissimilarity, or distance matrix.

**Syntax**

```
matrix dissimilarity matname = [varlist] [if] [in] [, options]
```

**Options**

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>measure</code></td>
<td>similarity or dissimilarity measure; default is L2 (Euclidean)</td>
</tr>
<tr>
<td><code>observations</code></td>
<td>compute similarities or dissimilarities between observations; the default</td>
</tr>
<tr>
<td><code>variables</code></td>
<td>compute similarities or dissimilarities between variables</td>
</tr>
<tr>
<td><code>names(varname)</code></td>
<td>row/column names for <code>matname</code> (allowed with observations)</td>
</tr>
<tr>
<td><code>allbinary</code></td>
<td>check that all values are 0, 1, or missing</td>
</tr>
<tr>
<td><code>proportions</code></td>
<td>interpret values as proportions of binary values</td>
</tr>
<tr>
<td><code>dissim(method)</code></td>
<td>change similarity measure to dissimilarity measure</td>
</tr>
</tbody>
</table>

where `method` transforms similarities to dissimilarities by using

- `oneminus` $d_{ij} = 1 - s_{ij}$
- `standard` $d_{ij} = \sqrt{s_{ii} + s_{jj} - 2s_{ij}}$

**Options**

- `measure` specifies one of the similarity or dissimilarity measures allowed by Stata. The default is L2, Euclidean distance. Many similarity and dissimilarity measures are provided for continuous data and for binary data; see `[MV] measure_option`.

- `observations` and `variables` specify whether similarities or dissimilarities are computed between observations or variables. The default is `observations`.

- `names(varname)` provides row and column names for `matname`. `varname` must be a string variable with a length of 32 or less in bytes. You will want to pick a `varname` that yields unique values for the row and column names. Uniqueness of values is not checked by `matrix dissimilarity`. `names()` is not allowed with the `variables` option. The default row and column names when the similarities or dissimilarities are computed between observations is `obs#`, where `#` is the observation number corresponding to that row or column.

- `allbinary` checks that all values are 0, 1, or missing. Stata treats nonzero values as one (excluding missing values) when dealing with what are supposed to be binary data (including binary similarity measures). `allbinary` causes `matrix dissimilarity` to exit with an error message if the values are not truly binary. `allbinary` is not allowed with `proportions` or the Gower `measure`.
proportions is for use with binary similarity measures. It specifies that values be interpreted as proportions of binary values. The default action treats all nonzero values as one (excluding missing values). With proportions, the values are confirmed to be between zero and one, inclusive. See [MV] measure_option for a discussion of the use of proportions with binary measures. proportions is not allowed with allbinary or the Gower measure.

**dissim(method)** specifies that similarity measures be transformed into dissimilarity measures. method may be oneminus or standard. oneminus transforms similarities to dissimilarities by using \( d_{ij} = 1 - s_{ij} \) (Kaufman and Rousseeuw 1990, 21). standard uses \( d_{ij} = \sqrt{s_{ii} + s_{jj} - 2s_{ij}} \) (Mardia, Kent, and Bibby 1979, 402). dissim() does nothing when the measure is already a dissimilarity or distance. See [MV] measure_option to see which measures are similarities.

---

**Remarks and examples**

Commands such as cluster singlelinkage, cluster completelinkage, and mds (see [MV] cluster and [MV] mds) have options allowing the user to select the similarity or dissimilarity measure to use for its computation. If you are developing a command that requires a similarity or dissimilarity matrix, the matrix dissimilarity command provides a convenient way to obtain it.

The similarity or dissimilarity between each observation (or variable if the variables option is specified) and the others is placed in matname. The element in the \( i \)th row and \( j \)th column gives either the similarity or dissimilarity between the \( i \)th and \( j \)th observation (or variable). Whether you get a similarity or a dissimilarity depends upon the requested measure; see [MV] measure_option.

If there are many observations (variables when the variables option is specified), you may need to increase the maximum matrix size; see [R] matsize. If the number of observations (or variables) is so large that storing the results in a matrix is not practical, you may wish to consider using the cluster measures command, which stores similarities or dissimilarities in variables; see [MV] cluster programming utilities.

When computing similarities or dissimilarities between observations, the default row and column names of matname are set to obs#, where # is the observation number. The names() option allows you to override this default. For similarities or dissimilarities between variables, the row and column names of matname are set to the appropriate variable names.

The order of the rows and columns corresponds with the order of your observations when you are computing similarities or dissimilarities between observations. Warning: If you reorder your data (for example, using sort or gsort) after running matrix dissimilarity, the row and column ordering will no longer match your data.

Another use of matrix dissimilarity is in performing a cluster analysis on variables instead of observations. The cluster command performs a cluster analysis of the observations; see [MV] cluster. If you instead wish to cluster variables, you can use the variables option of matrix dissimilarity to obtain a dissimilarity matrix that can then be used with clustermat; see [MV] clustermat and example 2 below.

**Example 1**

Example 1 of [MV] cluster linkage introduces data with four chemical laboratory measurements on 50 different samples of a particular plant. Let’s find the Canberra distance between the measurements performed by lab technician Bill found among the first 25 observations of the labtech dataset.
. use http://www.stata-press.com/data/r15/labtech
. matrix dissim D = x1 x2 x3 x4 if labtech=="Bill" in 1/25, canberra
. matrix list D

symmetric D[6,6]
        obs7     obs18     obs20     obs22     obs23     obs25
   obs7  0
   obs18 1.3100445  0
   obs20 1.1134916 .87626565  0
   obs22 1.452748  1.0363077 1.0621064  0
   obs23 1.0380665 1.4952796 .81602718 1.6888123  0
   obs25 1.4668898 1.5139834 1.4492336 1.0668425 1.1252514  0

By default, the row and column names of the matrix indicate the observations involved. The Canberra distance between the 23rd observation and the 18th observation is 1.4952796. See [MV] measure_option for a description of the Canberra distance.

Example 2

Example 2 of [MV] cluster linkage presents a dataset with 30 observations of 60 binary variables, a1, a2, ..., a30. In [MV] cluster linkage, the observations were clustered. Here we instead cluster the variables by computing the dissimilarity matrix by using matrix dissimilarity with the variables option followed by the clustermat command.

We use the matching option to obtain the simple matching similarity coefficient but then specify dissim(oneminus) to transform the similarities to dissimilarities by using the transformation \( d_{ij} = 1 - s_{ij} \). The allbinary option checks that the variables really are binary (0/1) data.

. use http://www.stata-press.com/data/r15/homework
. matrix dissim Avars = a*, variables matching dissim(oneminus) allbinary
. matrix subA = Avars[1..5,1..5]
. matrix list subA

symmetric subA[5,5]
         a1     a2     a3     a4     a5
    a1  0
    a2 .4  0
    a3 .4 .46666667  0
    a4 .3 .3  .36666667  0
    a5 .4 .4 .13333333 .3  0

We listed the first five rows and columns of the 60 × 60 matrix. The matrix row and column names correspond to the variable names.

To perform an average-linkage cluster analysis on the 60 variables, we supply the Avars matrix created by matrix dissimilarity to the clustermat averagelinkage command; see [MV] cluster linkage.
. clustermat averagelinkage Avars, clear
number of observations (_N) was 0, now 60
cluster name: _clus_1
. cluster generate g5 = groups(5)
. table g5

<table>
<thead>
<tr>
<th></th>
<th>Freq.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21</td>
</tr>
<tr>
<td>2</td>
<td>9</td>
</tr>
<tr>
<td>3</td>
<td>25</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
</tbody>
</table>

We generated a variable, g5, indicating the five-group cluster solution and then tabulated to show how many variables were clustered into each of the five groups. Group five has only one member.

. list g5 if g5==5

<table>
<thead>
<tr>
<th>g5</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>5</td>
</tr>
</tbody>
</table>

The member corresponds to the 13th observation in the current dataset, which in turn corresponds to variable a13 from the original dataset. It appears that a13 is not like the other variables.

Example 3

matrix dissimilarity drops observations containing missing values, except when the Gower measure is specified. The computation of the Gower dissimilarity between 2 observations is based on the variables where the 2 observations both have nonmissing values.

We illustrate using a dataset with 6 observations and 4 variables where only 2 of the observations have complete data.

. use http://www.stata-press.com/data/r15/gower, clear
. list

<table>
<thead>
<tr>
<th>b1</th>
<th>b2</th>
<th>x1</th>
<th>x2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>.76</td>
<td>.75</td>
</tr>
<tr>
<td>2</td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>.72</td>
<td>.88</td>
</tr>
<tr>
<td>4</td>
<td>.</td>
<td>1</td>
<td>.</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>.</td>
<td>.14</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
<td>0</td>
<td>.</td>
</tr>
</tbody>
</table>

. matrix dissimilarity matL2 = b* x*, L2
. matlist matL2, format(%8.3f)

<table>
<thead>
<tr>
<th>obs1</th>
<th>obs3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.000</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1.421</td>
</tr>
<tr>
<td></td>
<td>0.000</td>
</tr>
</tbody>
</table>
The resulting matrix is \( 2 \times 2 \) and provides the dissimilarity between observations 1 and 3. All other observations contained at least one missing value.

However, with the `gower` measure we obtain a \( 6 \times 6 \) matrix.

```plaintext
. matrix dissimilarity matgow = b1 b2 x1 x2, gower
. matlist matgow, format(%8.3f)

<table>
<thead>
<tr>
<th></th>
<th>obs1</th>
<th>obs2</th>
<th>obs3</th>
<th>obs4</th>
<th>obs5</th>
<th>obs6</th>
</tr>
</thead>
<tbody>
<tr>
<td>obs1</td>
<td>0.000</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>obs2</td>
<td></td>
<td>0.000</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>obs3</td>
<td>0.572</td>
<td></td>
<td>0.000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>obs4</td>
<td>0.500</td>
<td>0.944</td>
<td>0.000</td>
<td>0.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>obs5</td>
<td>0.412</td>
<td>1.000</td>
<td></td>
<td>0.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>obs6</td>
<td>0.528</td>
<td>0.491</td>
<td>0.708</td>
<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
</tr>
</tbody>
</table>
```

Because all the values for observation 2 are missing, the matrix contains missing values for the dissimilarity between observation 2 and the other observations. Notice the missing value in `matgow` for the dissimilarity between observations 4 and 5. There were no variables where observations 4 and 5 both had nonmissing values, and hence the `Gower` coefficient could not be computed.

**matrix eigenvalues — Eigenvalues of nonsymmetric matrices**

**Description**

*matrix eigenvalues* returns the real part of the eigenvalues in the $1 \times n$ row vector $r$ and the imaginary part of the eigenvalues in the $1 \times n$ row vector $c$. Thus the $j$th eigenvalue is $r[1,j] + i \cdot c[1,j]$.

The eigenvalues are sorted by their moduli; $r[1,1] + i \cdot c[1,1]$ has the largest modulus, and $r[1,n] + i \cdot c[1,n]$ has the smallest modulus.

If you want the eigenvalues for a symmetric matrix, see [P] *matrix symeigen*.

Also see [M-5] *eigensystem()* for alternative routines for obtaining eigenvectors and eigenvalues.

**Menu**

Data > Matrices, ado language > Eigenvalues of square matrices

**Syntax**

```
matrix eigenvalues r c = A
```

where $A$ is an $n \times n$ nonsymmetric, real matrix.

**Remarks and examples**

Typing *matrix eigenvalues r c = A* for $A$ $n \times n$ returns

\[
\begin{align*}
    r &= (r_1, r_2, \ldots, r_n) \\
    c &= (c_1, c_2, \ldots, c_n)
\end{align*}
\]

where $r_j$ is the real part and $c_j$ the imaginary part of the $j$th eigenvalue. The eigenvalues are part of the solution to the problem

\[
Ax_j = \lambda_j x_j
\]

and, in particular,

\[
\lambda_j = r_j + i \cdot c_j
\]

The corresponding eigenvectors, $x_j$, are not saved by *matrix eigenvalues*. The returned $r$ and $c$ are ordered so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$, where $|\lambda_j| = \sqrt{r_j^2 + c_j^2}$.  

373
Example 1

In time-series analysis, researchers often use eigenvalues to verify the stability of the fitted model.

Suppose that we have fit a univariate time-series model and that the stability condition requires the moduli of all the eigenvalues of a “companion” matrix \( A \) to be less than 1. (See Hamilton [1994] for a discussion of these models and conditions.)

First, we form the companion matrix.

```plaintext
. matrix A = (0.66151492, .2551595, .35603325, -.15403902, -.12734386)
. matrix A = A \ (I(4), J(4,1,0))
. matrix list A
```

Next we use `matrix eigenvalues` to obtain the eigenvalues, which we will then list:

```plaintext
. matrix eigenvalues re im = A
. matrix list re
```

Finally, we compute and list the moduli, which are all less than 1, although the first is close:

```plaintext
. forvalues i = 1/5 {
    2. display sqrt(re[1,`i']^2 + im[1,`i']^2)
    3. }
```

Methods and formulas

Stata’s internal eigenvalue extraction routine for nonsymmetric matrices is based on the public domain LAPACK routine DGEEV. Anderson et al. (1999) provide an excellent introduction to these routines. Stata’s internal routine also uses, with permission, f2c (©1990–1997 by AT&T, Lucent Technologies, and Bellcore).

References

Also see

[P] matrix — Introduction to matrix commands

[P] matrix symeigen — Eigenvalues and eigenvectors of symmetric matrices

[M-4] matrix — Matrix functions

[U] 14 Matrix expressions
matrix get — Access system matrices

Description

The `get()` matrix function obtains a copy of an internal Stata system matrix. Some system matrices can also be obtained more easily by directly referring to the returned result after a command. In particular, the coefficient vector can be referred to as `e(b)`, the variance–covariance matrix of estimators as `e(V)`, and the constraints matrix as `e(Cns)` after an estimation command.

`mat_put_rr` is a programmer’s command that posts `matname` as the internal `Rr` matrix. `matname` must have one more than the number of columns in the `e(b)` or `e(V)` matrices. The extra column contains the `r` vector, and the earlier columns contain the `R` matrix for the Wald test

\[ Rb = r \]

The matrix ...`get(Rr)` command provides a way to obtain the current `Rr` system matrix.

Syntax

* Obtain copy of internal Stata system matrix

\[ \texttt{matrix [define] matname = get(systemname)} \]

* Post matrix as internal `Rr` matrix

\[ \texttt{mat_put_rr matname} \]

where `systemname` is

- `_b` coefficients after any estimation command
- `VCE` covariance matrix of estimators after any estimation command
- `Rr` constraint matrix after `test`; see `[R] test`
- `Cns` constraint matrix after any estimation command

Remarks and examples

`get()` obtains copies of matrices containing coefficients and the covariance matrix of the estimators after estimation commands (such as `regress` and `probit`) and obtains copies of matrices left behind by other Stata commands. The other side of `get()` is `ereturn post`, which allows ado-file estimation commands to post results to Stata’s internal areas; see `[P] ereturn.`
Example 1

After any model-fitting command, the coefficients are available in _b and the variance–covariance matrix of the estimators in VCE.

```
. use http://www.stata-press.com/data/r15/auto
(1978 Automobile Data)
. regress price weight mpg
(output omitted)
```

Here we can directly use `e(b)` and `e(V)` to obtain the matrices:

```
. matrix list e(b)
e(b)[1,3]
   weight   mpg   _cons
    y1  1.7465592 -49.512221  1946.0687
. matrix list e(V)
symmetric e(V)[3,3]
   weight   mpg   _cons
    weight  .41133468
    mpg     44.601659  7422.863
   _cons   -2191.9032 -292759.82   12938766
```

We can also use the matrix get() function to obtain these matrices:

```
. matrix b = get(_b)
. matrix V = get(VCE)
. matrix list b
b[1,3]
   weight   mpg   _cons
    y1  1.7465592 -49.512221  1946.0687
. matrix list V
symmetric V[3,3]
   weight   mpg   _cons
    weight  .41133468
    mpg     44.601659  7422.863
   _cons   -2191.9032 -292759.82  12938766
```

The columns of `b` and both dimensions of `V` are properly labeled.
Example 2

After \texttt{test}, the restriction matrix is available in \texttt{Rr}. Having just estimated a regression of \texttt{price} on \texttt{weight} and \texttt{mpg}, we will run a test and then get the restriction matrix:

\begin{verbatim}
. test weight=1, notest
   ( 1) weight = 1
. test mpg=40, accum
   ( 1) weight = 1
   ( 2) mpg = 40
       F(  2,   71) =  6.29
       Prob > F =  0.0030
. matrix rxtr=get(Rr)
. matrix list rxtr
rxtr[2,4]  
    c1   c2   c3   c4
   r1    1   0   0    1
   r2    0   1   0   40
\end{verbatim}

[P] \texttt{matrix} — Introduction to matrix commands

[U] 13.5 Accessing coefficients and standard errors

[U] 14 Matrix expressions
Description

`mkmat` stores the variables listed in `varlist` in column vectors of the same name, that is, $N \times 1$ matrices, where $N = _N$, the number of observations in the dataset. Optionally, they can be stored as an $N \times k$ matrix, where $k$ is the number of variables in `varlist`. The variable names are used as column names. By default, the rows are named `r1, r2, ...`

`s vmax` takes a matrix and stores its columns as new variables. It is the reverse of the `mkmat` command, which creates a matrix from existing variables.

`matname` renames the rows and columns of a matrix. `matname` differs from the `matrix rownames` and `matrix colnames` commands in that `matname` expands varlist abbreviations and allows a restricted range for the rows or columns. See `[P] matrix rownames`.

Menu

`mkmat`
Data > Matrices, ado language > Convert variables to matrix

`svmat`
Data > Matrices, ado language > Convert matrix to variables

Syntax

Create matrix from variables

```
mkmat `varlist' [if] [in] [, matrix(matname) nomissing rownames(varname)
roweq(varname) rowprefix(string) obs nchar(#)]
```

Create variables from matrix

```
svmat [type] `A' [, names(col|eqcol|matcol|string)]
```

Rename rows and columns of matrix

```
matname `A' namelist [, rows(range) columns(range) explicit]
```

where `A` is the name of an existing matrix, `type` is a storage type for the new variables, and `namelist` is one of 1) a varlist, that is, names of existing variables possibly abbreviated; 2) `_cons` and the names of existing variables possibly abbreviated; or 3) arbitrary names when the `explicit` option is specified.
To reset problem-size limits, see [R] matsize.

Options

matrix(matname) requests that the vectors be combined in a matrix instead of creating the column vectors.

nomissing specifies that observations with missing values in any of the variables be excluded (“listwise deletion”).

rownames(varname) and roweq(varname) specify that the row names and row equations of the created matrix or vectors be taken from varname. varname should be a string variable or an integer positive-valued numeric variable. [Value labels are ignored; use decode (see [D] encode) if you want to use value labels.] Within the names, spaces and periods are replaced by an underscore (_).

rowprefix(string) specifies that the string string be prefixed to the row names of the created matrix or column vectors. In the prefix, spaces and periods are replaced by an underscore (_). If rownames() is not specified, rowprefix() defaults to r, and to nothing otherwise.

obs specifies that the observation numbers be used as row names. This option may not be combined with rownames().

nchar(#) specifies that row names be truncated to # characters, 1 ≤ # ≤ 32. The default is nchar(32).

names(col|eqcol|matcol|string) specifies how the new variables are to be named.

names(col) uses the column names of the matrix to name the variables.

names(eqcol) uses the equation names prefixed to the column names.

names(matcol) uses the matrix name prefixed to the column names.

names(string) names the variables string1, string2, ..., stringn, where string is a user-specified string and n is the number of columns of the matrix.

If names() is not specified, the variables are named A1, A2, ..., An, where A is the name of the matrix.

rows(range) and columns(range) specify the rows and columns of the matrix to rename. The number of rows or columns specified must be equal to the number of names in namelist. If both rows() and columns() are given, the specified rows are named namelist, and the specified columns are also named namelist. The range must be given in one of the following forms:

- rows(.) renames all the rows
- rows(2..8) renames rows 2–8
- rows(3) renames only row 3
- rows(4...) renames row 4 to the last row

If neither rows() nor columns() is given, rows(.) columns(.) is the default. That is, the matrix must be square, and both the rows and the columns are named namelist.

explicit suppresses the expansion of varlist abbreviations and omits the verification that the names are those of existing variables. That is, the names in namelist are used explicitly and can be any valid row or column names.

Remarks and examples

Remarks are presented under the following headings:

mkmat
svmat
Although cross products of variables can be loaded into a matrix with the `matrix accum` command (see [P] `matrix accum`), programmers may sometimes find it more convenient to work with the variables in their datasets as vectors instead of as cross products. `mkmat` allows the user a simple way to load specific variables into matrices in Stata’s memory.

### Example 1

`mkmat` uses the variable name to name the single column in the vector. This feature guarantees that the variable name will be carried along in any additional matrix calculations. This feature is also useful when vectors are combined in a general matrix.

If the variables contain missing values, so will the corresponding matrix or matrices. Many matrix commands, such as the matrix inversion functions \texttt{inv()} and \texttt{invsym()}, do not allow missing values in matrices. If you specify the \texttt{nomissing} option, \texttt{mkmat} will exclude observations with missing values so that subsequent matrix computations will not be hampered by missing values. Listwise deletion parallels missing-value handling in most Stata commands.

\section*{Technical note}

\texttt{mkmat} provides a useful addition to Stata’s matrix commands, but it will work only with small datasets.

Stata limits matrices to no more than \texttt{matsize} \times \texttt{matsize}, which means a maximum of \(800 \times 800\) for Stata/IC and \(11,000 \times 11,000\) for Stata/SE and Stata/MP. By limiting Stata’s matrix capabilities to \texttt{matsize} \times \texttt{matsize}, has not Stata’s matrix language itself been limited to datasets no larger than \texttt{matsize}? It would certainly appear so; in the simple matrix calculation for regression coefficients \((X'X)^{-1}X'y\), \(X\) is an \(n \times k\) matrix (\(n\) being the number of observations and \(k\) being the number of variables), and given the \texttt{matsize} constraint, \(n\) must be less than 800 (or up to 11,000 in Stata/MP and Stata/SE).

Our answer is as follows: yes, \(X\) is limited in the way stated, but \(X'X\) is a mere \(k \times k\) matrix, and, similarly, \(X'y\) is only \(k \times 1\). Both of these matrices are well within Stata’s matrix-handling capabilities, and the \texttt{matrix accum} command (see [P] \texttt{matrix accum}) can directly create both of them.

Moreover, even if Stata could hold the \(n \times k\) matrix \(X\), it would still be more efficient to use \texttt{matrix accum} to form \(X'X\). \(X'X\), interpreted literally, says to load a copy of the dataset, transpose it, load a second copy of the dataset, and then form the matrix product. Thus two copies of the dataset occupy memory in addition to the original copy Stata already had available (and from which \texttt{matrix accum} could directly form the result with no additional memory use). For small \(n\), the inefficiency is not important, but for large \(n\), the inefficiency could make the calculation infeasible. For instance, with \(n = 12,000\) and \(k = 6\), the additional memory use is 1,125 kilobytes.

More generally, matrices in statistical applications tend to have dimensions \(k \times k\), \(n \times k\), and \(n \times n\), with \(k\) small and \(n\) large. Terms dealing with the data are of the generic form \(X'_{k_1 \times n} W_{n \times n} Z_{n \times k_2}\). \((X'X\) fits the generic form with \(X = X\), \(W = I\), and \(Z = X\).) Matrix programming languages cannot deal with the deceptively simple calculation \(X'WZ\) because of the staggering size of the \(W\) matrix. For \(n = 12,000\), storing \(W\) requires a little more than a gigabyte of memory. In statistical formulas, however, \(W\) is given by formula and, in fact, never needs to be stored in its entirety. Exploitation of this fact is all that is needed to resurrect the use of a matrix programming language in statistical applications. Matrix programming languages may be inefficient because of copious memory use, but in statistical applications, the inefficiency is minor for matrices of size \(k \times k\) or smaller. Our design of the various \texttt{matrix accum} commands allows calculating terms of the form \(X'WZ\), and this one feature is all that is necessary to allow efficient and robust use of matrix languages.

Programs for creating data matrices, such as that offered by \texttt{mkmat}, are useful for pedagogical purposes and for a specific application where Stata’s \texttt{matsize} constraint is not binding, it seems so natural. On the other hand, it is important that general tools not be implemented by forming data matrices because such tools will be drastically limited in dataset size. Coding the problem in terms of the various \texttt{matrix accum} commands (see [P] \texttt{matrix accum}) is admittedly more tedious, but by abolishing data matrices from your programs, you will produce tools suitable for use on large datasets.
Example 2

Let's get the vector of coefficients from a regression and use `svmat` to save the vector as a new variable, save the dataset, load the dataset back into memory, use `mkmat` to create a vector from the variable, and finally, use `matname` to rename the columns of the row vector.

```
. use http://www.stata-press.com/data/r15/auto
   (1978 Automobile Data)
. quietly regress mpg weight gear_ratio foreign
. matrix b = get(_b)

[P] matrix — Introduction to matrix commands

[P] matrix accum — Form cross-product matrices

[M-4] stata — Stata interface functions

[U] 14 Matrix expressions
matrix rownames — Name rows and columns

Description

matrix rownames and colnames reset the row and column names of an already existing matrix.

matrix roweq and coleq also reset the row and column names of an already existing matrix, but if a simple name (a name without a colon) is specified, it is interpreted as an equation name.

In either case, the part of the name not specified is left unchanged.

Syntax

Reset row names of matrix

\[
\text{matrix rownames } A = \text{names}
\]

Reset column names of matrix

\[
\text{matrix colnames } A = \text{names}
\]

Reset row names and interpret simple names as equation names

\[
\text{matrix roweq } A = \text{names}
\]

Reset column names and interpret simple names as equation names

\[
\text{matrix coleq } A = \text{names}
\]

where name can be

- a simple name;
- a colon follow by a simple name;
- an equation name followed by a colon; or
- an equation name, a colon, and a simple name.

and a simple name may be augmented with time-series operators and factor-variable specifications.

Remarks and examples

See \[U\] 14.2 Row and column names for a description of the row and column names bordering a matrix.
Example 1

In general, the names bordering matrices are set correctly by Stata because of the tracking of the matrix algebra, and you will not need to reset them. Nevertheless, imagine that you have formed $X'X$ in the matrix named $XX$ and that it corresponds to the underlying variables price, weight, and mpg:

```
.matrix list XX
symmetric XX[3,3]
   c1     c2     c3
r1  3.448e+09
r2  1.468e+09  7.188e+08
r3  9132716   4493720   36008
```

You did not form this matrix with `matrix accum` because, had you done so, the rows and columns would already be correctly named. However you formed it, you now want to reset the names:

```
.matrix rownames XX = price weight mpg
.matrix colnames XX = price weight mpg
.matrix list XX
symmetric XX[3,3]
   price  weight  mpg
   price  3.448e+09
   weight  1.468e+09  7.188e+08
   mpg  9132716   4493720   36008
```

Example 2

We now demonstrate setting the equation names and names with time-series operators.

```
.matrix list AA
symmetric AA[4,4]
   c1     c2     c3     c4
r1  .2967663
r2  .03682017  .57644416
r3  -.87052852  .32713601  20.274957
r4  -1.572579  -.63830843  -12.150097  26.099582
.matrix rownames AA = length L3D2.length mpg L.mpg
.matrix colnames AA = length L3D2.length mpg L.mpg
.matrix roweq AA = eq1 eq1 eq2 eq2
.matrix coleq AA = eq1 eq1 eq2 eq2
.matrix list AA
symmetric AA[4,4]
eq1:length  L3D2.  length  mpg  L.mpg
eq1:length  .2967663
   eq1:L3D2.length  .03682017  .57644416
   eq1:mpg  -.87052852  .32713601  20.274957
   eq1:L.mpg  -1.572579  -.63830843  -12.150097  26.099582
Factor variables and interactions are much like time-series–operated variables, we specify each level variable.

```stata
. mat rownames AA = 0b.foreign 1.foreign 0.foreign#c.mpg 1.foreign#c.mpg
. mat colnames AA = 0b.foreign 1.foreign 0.foreign#c.mpg 1.foreign#c.mpg
```

As in factor-variable varlists, we can combine any time-series lead and lag operators with factor variables.

```stata
. mat rownames XX = 0bL2.foreign 1L2.foreign 0L3.foreign#cL3.mpg
> 1L3.foreign#cL3.mpg
. mat colnames XX = 0bL2.foreign 1L2.foreign 0L3.foreign#cL3.mpg
> 1L3.foreign#cL3.mpg
```

Technical note

`matrix rownames` and `colnames` sometimes behave in surprising ways:

1. If your list of names includes no colons—does not mention the equation names—whatever equation names are in place are left in place; they are not changed.

2. If your list of names has every name ending in a colon—so that it mentions only the equation names and not the subnames—whatever subnames are in place are left in place; they are not changed.

3. If your list of names has fewer names than are required to label all the rows or columns, the last name in the list is replicated. (If you specify too many names, you will get the conformability error message, and no names will be changed.)

4. `matrix rownames` and `matrix colnames` that are not interactions are limited to 32 characters, exclusive of time-series and factor-variable operators. Each component of an interaction is limited to 32 characters, exclusive of operators.

These surprises have their uses, but if you make a mistake, the result really may surprise you. For instance, rule 3, by itself, is just odd. Combined with rule 2, however, rule 3 allows you to set all the equation names in a matrix easily. If you type `matrix rownames XX = myeq:`, all the equation names in the row are reset while the subnames are left unchanged:

```stata
. matrix rownames XX = myeq:
. matrix list XX
  symmetric XX[3,3]
    price     weight     mpg
  myeq:price  3.448e+09
  myeq:weight 1.468e+09  7.188e+08
  myeq:mpg   9132716    4493720    36008
```

Setting equation names is often done before forming a partitioned matrix so that, when the components are assembled, each has the correct equation name.

Thus to review, to get the result above, we could have typed

```stata
. matrix rownames XX = myeq:price myeq:weight myeq:mpg
```

or

```stata
. matrix rownames XX = price weight mpg
. matrix rownames XX = myeq:
```
or even

```
.matrix rownames XX = myeq:
.matrix rownames XX = price weight mpg
```

All would have resulted in the same outcome. The real surprise comes, however, when you make a mistake:

```
.matrix rownames XX = myeq:
.matrix rownames XX = price weight
.matrix list XX
```

```
symmetric XX[3,3]
    price    weight   mpg
myeq:price  3.448e+09
myeq:weight  1.468e+09  7.188e+08
myeq:weight  9132716   4493720   36008
```

Our mistake above is that we listed only two names for the subnames of the rows of XX and matrix rownames and then labeled both of the last rows with the subname weight.

### Technical note

The equation name `_:` by itself is special; it means the null equation name. For instance, as of the last technical note, we were left with

```
.matrix list XX
```

```
symmetric XX[3,3]
    price    weight   mpg
myeq:price  3.448e+09
myeq:weight  1.468e+09  7.188e+08
myeq:weight  9132716   4493720   36008
```

Let’s fix it:

```
.matrix rownames XX = price weight mpg
.matrix rownames XX = _:
.matrix list XX
```

```
symmetric XX[3,3]
    price    weight   mpg
price     3.448e+09
weight    1.468e+09  7.188e+08
mpg       9132716   4493720   36008
```

### Technical note

matrix roweq and matrix coleq are really the same commands as matrix rownames and matrix colnames. They differ in only one respect: if a specified name does not contain a colon, matrix roweq and matrix coleq interpret that name as if it did end in a colon.

matrix rownames, matrix colnames, matrix roweq, and matrix coleq are often used in conjunction with the rowfullnames, colfullnames, rownames, colnames, roweq, and coleq extended macro functions introduced in [P] matrix define. The rownames and colnames extended macro functions return only the name, including any time-series or factor-variable operators, but not the equation name.
. matrix list AA
symmetric AA[4,4]

eq1: eq1: eq2: eq2:
L3D2. length length mpg mpg

length .2967663
L3D2.length .03682017 .57644416
eq2:mpg -.87052852 .32713601 20.274957
eq2:L.mpg -1.572579 -.63830843 -12.150097 26.099582

. local rsubs : rownames AA
. display "The row subnames of AA are -- 'rsubs' --"
The row subnames of AA are -- length L3D2.length mpg L.mpg --

Similarly, the roweq extended macro function returns only the equation names without the trailing colon:

. local reqs : roweq AA
. display "The row equations of AA are -- 'reqs' --"
The row equations of AA are -- eq1 eq1 eq2 eq2 --

Now consider the problem that you have two matrices named A and B that have the same number of rows. A is correctly labeled and includes equation names. You want to copy the complete names of A to B. You might be tempted to type

. local names : rownames A
. matrix rownames B = 'names'

This is not adequate. You will have copied the names but not the equation names. To copy both parts of the complete names, you can type

. local subs : rownames A
. local eqs : roweq A
. matrix rownames B = 'subs'
. matrix roweq B = 'eqs'

This method can be used even when there might not be equation names. The equation name _ is special; not only does setting an equation to that name remove the equation name, but when there is no equation name, the roweq and coleq extended macro functions return that name.

A better way to copy the names is to use the rowfullnames and colfullnames extended macro functions (see [P] matrix define and [P] macro). You can more compactly type

. local rname : rowfullnames A
. matrix rownames B = 'rname'

Also see

[P] macro — Macro definition and manipulation
[P] matrix — Introduction to matrix commands
[P] matrix define — Matrix definition, operators, and functions
[U] 14 Matrix expressions
matrix score — Score data from coefficient vectors

Description

`matrix score` creates \( \text{newvar}_j = x_j b' \) (\( b \) being a row vector), where \( x_j \) is the row vector of values of the variables specified by the column names of \( b \). The name `_cons` is treated as a variable equal to 1.

Syntax

```
matrix score [type] newvar = b [if] [in]
[, equation(#|eqname) missval(#) replace forcezero]
```

where \( b \) is a \( 1 \times p \) matrix.

Options

- `equation(#|eqname)` specifies the equation—by either number or name—for selecting coefficients from \( b \) to use in scoring. See [U] 14.2 Row and column names and [P] matrix rownames for more on equation labels with matrices.

- `missval(#)` specifies the value to be assumed if any values are missing from the variables referred to by the coefficient vector. By default, this value is taken to be missing (.), and any missing value among the variables produces a missing score.

- `replace` specifies that `newvar` already exists. Here observations not included by `if exp` and `in range` are left unchanged; that is, they are not changed to missing. Be warned that `replace` does not promote the storage type of the existing variable; if the variable was stored as an `int`, the calculated scores would be truncated to integers when stored.

- `forcezero` specifies that, should a variable described by the column names of \( b \) not exist, the calculation treat the missing variable as if it did exist and was equal to zero for all observations. It contributes nothing to the summation. By default, a missing variable would produce an error message.

Remarks and examples

Scoring refers to forming linear combinations of variables in the data with respect to a coefficient vector. For instance, let’s create and then consider the vector `coefs`:

```
. use http://www.stata-press.com/data/r15/auto
    (1978 Automobile Data)
. quietly regress price weight mpg
. matrix coefs = e(b)
. matrix list coefs
   coefs[1,3]
     weight    mpg    _cons
     y1  1.7465592 -49.512221  1946.0687
```

390
Scoring the data with this vector would create a new variable equal to the linear combination

\[ 1.7465592 \text{ weight} - 49.512221 \text{ mpg} + 1946.0687 \]

The vector is interpreted as coefficients; the corresponding names of the variables are obtained from the column names (row names if `coefs` were a column vector). To form this linear combination, we type

```
. matrix score lc = coefs
. summarize lc
```

If the coefficient vector has equation names, `matrix score` with the `eq()` option selects the appropriate coefficients for scoring. `eq(#1)` is assumed if no `eq()` option is specified.

```
. quietly sureg (price weight mpg) (displacement weight)
. matrix coefs = e(b)
. matrix list coefs
```

```
coefs[1,5]
price: price: price:
  weight mpg _cons weight _cons
y1   1.7358275 -51.298248 2016.5101 .10574552 -121.99702
```

```
. matrix score lcnoeq = coefs
. matrix score lca = coefs, eq(price)
. matrix score lc1 = coefs, eq(#1)
. matrix score lcb = coefs, eq(displacement)
. matrix score lc2 = coefs, eq(#2)
. summarize lcnoeq lca lc1 lcb lc2
```

```
Variable | Obs  | Mean    | Std. Dev. | Min | Max
---------|------|---------|-----------|-----|-----
lcnoeq   | 74   | 6165.257| 1597.606  | 3406.46 | 9805.269 |
lca      | 74   | 6165.257| 1597.606  | 3406.46 | 9805.269 |
lc1      | 74   | 6165.257| 1597.606  | 3406.46 | 9805.269 |
lc2      | 74   | 6165.257| 1597.606  | 3406.46 | 9805.269 |
lc2      | 74   | 6165.257| 1597.606  | 3406.46 | 9805.269 |
```

Technical note

If the same equation name is scattered in different sections of the coefficient vector, the results may not be what you expect.

```

Coefficient vectors created by Stata estimation commands will have equation names together.

Also see

[P] matrix — Introduction to matrix commands
[U] 14 Matrix expressions
**matrix svd — Singular value decomposition**

### Description

*matrix svd* produces the singular value decomposition (SVD) of *A*.

Also see [M-5] svd() for alternative routines for obtaining the singular value decomposition.

### Menu

Data > Matrices, ado language > Singular value decomposition

### Syntax

```plaintext
matrix svd U w V = A
```

where *U*, *w*, and *V* are matrix names (the matrices may exist or not) and *A* is the name of an existing *m* × *n* matrix, *m* ≥ *n*.

### Remarks and examples

The singular value decomposition of *m* × *n* matrix *A*, *m* ≥ *n*, is defined as

\[ A = U \text{diag}(w)V' \]

*U*: *m* × *n*, *w*: 1 × *n*, diag(*w*): *n* × *n*, and *V*: *n* × *n*, where *U* is column orthogonal (*U'U = I* if *m* = *n*), all the elements of *w* are positive or zero, and *V'V = I*.

Singular value decomposition can be used to obtain a g2-inverse of *A* (*A**: *n* × *m*, such that *AA*A = *A* and *A*A*A* = *A*—the first two Moore–Penrose conditions) via *A* = *V*{diag(1/*w*)} *U*' where 1/*w* refers to individually taking the reciprocal of the elements of *w* and substituting 0 if *w* = 0 or is small. If *A* is square and of full rank, *A* = *A*⁻¹.
Example 1

Singular value decomposition is used to obtain accurate inverses of nearly singular matrices and to obtain $g_2$-inverses of matrices that are singular, to construct orthonormal bases, and to develop approximation matrices. Our example will prove that \texttt{matrix svd} works:

\begin{verbatim}
. matrix A = (1,2,9\2,7,5\2,4,18)
. matrix svd U w V = A
. matrix list U
U[3,3]
c1 c2 c3

As claimed, \texttt{newA} is equal to our original \texttt{A}.

The $g_2$-inverse of \texttt{A} is computed below. The second element of \texttt{w} is small, so we decide to set the corresponding element of $\text{diag}(1/w_j)$ to zero. We then show that the resulting \texttt{Ainv} matrix has the properties of a $g_2$-inverse for \texttt{A}.

### Description

`matrix symeigen` returns the eigenvectors in the columns of `X`: \( n \times n \) and the corresponding eigenvalues in `v`: \( 1 \times n \). The eigenvalues are sorted: \( v[1,1] \) contains the largest eigenvalue (and \( X[1...,1] \) its corresponding eigenvector), and \( v[1,n] \) contains the smallest eigenvalue (and \( X[1...,n] \) its corresponding eigenvector).

If you want the eigenvalues for a nonsymmetric matrix, see [P] `matrix eigenvalues`.

Also see [M-5] `eigensystem()` for other routines for obtaining eigenvalues and eigenvectors.

### Menu

Data > Matrices, ado language > Eigenvalues and eigenvectors of symmetric matrices

### Syntax

```
matrix symeigen X v = A
```

where `A` is an \( n \times n \) symmetric matrix.

### Remarks and examples

Typing `matrix symeigen X v = A` for `A`: \( n \times n \) returns

\[
v = (\lambda_1, \lambda_2, \ldots, \lambda_n)
\]

\[
X = (x_1, x_2, \ldots, x_n)
\]

where \( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_n \). Each \( x_i \) and \( \lambda_i \) is a solution to

\[Ax_i = \lambda_ix_i\]

or, more compactly,

\[AX = X \text{diag}(v)\]

### Example 1

Eigenvalues and eigenvectors have many uses. We will demonstrate that `symeigen` returns matrices meeting the definition:

```
. use http://www.stata-press.com/data/r15/auto
(1978 Automobile Data)
.
. matrix accum A = weight mpg length, noconstant deviation
```

(\( \text{obs}=74 \))
Methods and formulas

Stata’s internal eigenvalue and eigenvector extraction routines are translations of the public domain EISPACK routines, Smith et al. (1976), which are in turn based on Wilkinson and Reinsch (1971). EISPACK was developed under contract for the Office of Scientific and Technical Information, U.S. Department of Energy, by Argonne National Laboratory and supported by funds provided by the Nuclear Regulatory Commission. Stata’s use of these routines is by permission of the National Energy Software Center of the Argonne National Laboratory. A brief but excellent introduction to the techniques used by these routines can be found in Press et al. (2007, 563–599).

[M-4] matrix — Matrix functions

[U] 14 Matrix expressions
matrix utility — List, rename, and drop matrices

Description

matrix dir lists the names of currently existing matrices. matrix list lists the contents of a matrix. matrix rename changes the name of a matrix. matrix drop eliminates a matrix.

Menu

matrix list
Data > Matrices, ado language > List contents of matrix

matrix rename
Data > Matrices, ado language > Rename matrix

matrix drop
Data > Matrices, ado language > Drop matrices

Syntax

List matrix names

matrix dir

List contents of matrix

matrix list mname [ , noblank nohalf noheader nonames format(%fmt) title(string) nodotz ]

Rename matrix

matrix rename oldname newname

Drop matrix

matrix drop { _all | mnames }
Options

-noblank suppresses printing a blank line before printing the matrix. This is useful in programs.

-nohalf specifies that, even if the matrix is symmetric, the full matrix be printed. The default is to print only the lower triangle in such cases.

-noheader suppresses the display of the matrix name and dimension before the matrix itself. This is useful in programs.

-nonames suppresses the display of the bordering names around the matrix.

-format(\%fmt) specifies the format to be used to display the individual elements of the matrix. The default is format(\%10.0g).

-title(string) adds the specified title string to the header displayed before the matrix itself. If noheader is specified, title() does nothing because displaying the header is suppressed.

-nodotz specifies that .z missing values be displayed as blanks.

Remarks and examples

Example 1

In the example below, matrix list normally displays only the lower half of symmetric matrices. nohalf prevents this.

. matrix b = (2, 5, 4 \ 5, 8, 6 \ 4, 6, 3)
. matrix a = (1, 2 \ 2, 4)
. matrix dir
   a[2,2]
   b[3,3]
. matrix rename a z
. matrix dir
   z[2,2]
   b[3,3]
. matrix list b
   symmetric b[3,3]
   c1  c2  c3
   r1  2
   r2  5  8
   r3  4  6  3
. matrix list b, nohalf
   symmetric b[3,3]
   c1  c2  c3
   r1  2  5  4
   r2  5  8  6
   r3  4  6  3
. matrix drop b
. matrix dir
   z[2,2]
. matrix drop _all
. matrix dir
 Technical note

When writing programs and using matrix names obtained through `tempname` (see [P] `macro`), it is not necessary to explicitly drop matrices; the matrices are removed automatically at the conclusion of the program.

```stata
. program define example
 1.   tempname a
 2.   matrix `a' = (1,2\3,4) /* this is temporary */
 3.   matrix b = (5,6\7,8) /* and this permanent */
 4.   display "The temporary matrix a contains"
 5.   matrix list `a', noheader
 6.   end

.example
The temporary matrix a contains
  c1  c2
 r1  1  2
 r2  3  4

. matrix dir
   b[2,2]
```

Nevertheless, dropping matrices with temporary names in programs when they are no longer needed is recommended, unless the program is about to exit (when they will be dropped anyway). Matrices consume memory; dropping them frees memory.

[P] `matlist' — Display a matrix and control its format

[P] `matrix' — Introduction to matrix commands

[U] 14 Matrix expressions
Description

more causes Stata to display —more— and pause until any key is pressed if more is set on and does nothing if more is set off.

The current value of set more is stored in c(more); see [P] creturn.
See [R] more for information on set more on and set more off.

Syntax

more

Remarks and examples

Ado-file programmers need take no special action to have —more— conditions arise when the screen is full. Stata handles that automatically if you have indicated you wish to have —more— conditions by specifying set more on.

If, however, you wish to force a —more— condition early, you can include the more command in your program. The syntax of more is

more

more takes no arguments.

[P] sleep — Pause for a specified time
[R] query — Display system parameters
[U] 7 —more— conditions
Description

Some Stata commands have a `nopreserve` option. This option is for use by programmers when `stata_command` is used as a subroutine of another command.

Syntax

```
stata_command ... [, ... nopreserve ...]
```

Option

`nopreserve` specifies that `stata_command` need not bother to `preserve` the data in memory. The usual situation is that `stata_command` is being used as a subroutine by another program, the data in memory have been preserved by the caller, and the caller will not need to access the data again before the data are restored from the caller’s preserved copy.

Remarks and examples

Some commands change the data in memory in the process of performing their task even though the command officially does not change the data in memory. Such commands achieve this by using `preserve` to make a temporary copy of the data on disk, which is later restored to memory.

Even some commands whose entire purpose is to make a modification to the data in memory sometimes make temporary copies of the data just in case the user should press `Break` while the changes to the data are still being completed.

This is done using `preserve`; see [P] `preserve`.

Assume `alpha` and `beta` are each implemented using `preserve`. Assume that `alpha` uses `beta` as a subroutine. If `alpha` itself does not intend to use the data after calling `beta`, then `beta` preserving and restoring the data is unnecessary because `alpha` already has preserved the data from which memory will be restored. Then `alpha` should specify the `nopreserve` option when calling `beta`.

Also see

[P] `preserve` — Preserve and restore data
numlist — Parse numeric lists

Description

The numlist command expands the numeric list supplied as a string argument and performs error checking based on the options specified. Any numeric sequence operators in the numlist string are evaluated, and the expanded list of numbers is returned in r(numlist). See [U] 11.1.8 numlist for a discussion of numeric lists.

Syntax

```
numlist "numlist" [, ascending descending integer missingokay min(#) max(#)
range(operator# [ operator#]) sort]
```

where numlist consists of one or more numlist_elements shown below

and where operator is  

```
< | <= | > | >=
```

There is no space between operator and #; for example,

```
range(>=0)
range(>0 <=50)
```

<table>

</tbody>
</table>
Options

ascending indicates that the user must give the numeric list in ascending order without repeated values. This is different from the sort option.

descending indicates that the numeric list must be given in descending order without repeated values.

integer specifies that the user may give only integer values in the numeric list.

missingokay indicates that missing values are allowed in the numeric list. By default, missing values are not allowed.

min(#) specifies the minimum number of elements allowed in the numeric list. The default is min(1). If you want to allow empty numeric lists, specify min(0).

max(#) specifies the maximum number of elements allowed in the numeric list. The default is max(1600), which is the largest allowed maximum.

range(operator # [ operator # ]) specifies the acceptable range for the values in the numeric list. The operators are < (less than), <= (less than or equal to), > (greater than), and >= (greater than or equal to). No space is allowed between the operator and the #.

sort specifies that the returned numeric list be sorted. This is different from the ascending option, which places the responsibility for providing a sorted list on the user who will not be allowed to enter a nonsorted list. sort, on the other hand, puts no restriction on the user and takes care of sorting the list. Repeated values are also allowed with sort.

Remarks and examples

Programmers rarely use the numlist command because syntax also expands numeric lists, and it handles the rest of the parsing problem, too, at least if the command being parsed follows standard syntax. numlist is used for expanding numeric lists when what is being parsed does not follow standard syntax.

Example 1

We demonstrate the numlist command interactively.

```
. numlist "5.3 1.0234 3 6:18 -2.0033 5.3/7.3"
. display 'r(numlist)''
5.3 1.0234 3 6 9 12 15 18 -2.0033 5.3 6.3 7.3
. numlist "5.3 1.0234 3 6:18 -2.0033 5.3/7.3", integer
invalid numlist has noninteger elements
r(126);
. numlist "1 5 8/12 15", integer descending
invalid numlist has elements out of order
r(124);
. numlist "1 5 8/12 15", integer ascending
. display 'r(numlist)''
1 5 8 9 10 11 12 15
```
. numlist "100 1 5 8/12 15", integer ascending
invalid numlist has elements out of order
r(124);
. numlist "100 1 5 8/12 15", integer sort
. display "r(numlist)"
1 5 8 9 10 11 12 15 100
. numlist "3 5 . 28 -3(2)5"
invalid numlist has missing values
r(127);
. numlist "3 5 . 28 -3(2)5", missingokay min(3) max(25)
. display "r(numlist)"
3 5 . 28 -3 -1 1 3 5
. numlist "28 36", min(3) max(6)
invalid numlist has too few elements
r(122);
. numlist "28 36 . 5 2.8 7 32 -8", min(3) max(6)
invalid numlist has too many elements
r(123);
. numlist "3/6 -4 -1 to 5", range(>=1)
invalid numlist has elements outside of allowed range
r(125);
. numlist "3/6", range(>=0 <30)
. display "r(numlist)"
3 4 5 6

Stored results
numlist stores the following in r():

Macros
r(numlist) expanded numeric list

[P] syntax — Parse Stata syntax
[U] 11.1.8 numlist
pause — Program debugging command

**Description**

If pause is on, the `pause [message]` command displays `message` and temporarily suspends execution of the program, returning control to the keyboard. Execution of keyboard commands continues until you type `end` or `q`, at which time execution of the program resumes. Typing `BREAK` in pause mode (as opposed to pressing the Break key) also resumes program execution, but the break signal is sent to the calling program.

If pause is off, `pause` does nothing.

Pause is off by default. Type `pause on` to turn pause on. Type `pause off` to turn it back off.

**Syntax**

```
pause { on | off | [ message ] }
```

**Remarks and examples**

`pause` assists in debugging Stata programs. The line `pause` or `pause message` is placed in the program where problems are suspected (more than one `pause` may be placed in a program). For instance, you have a program that is not working properly. A piece of this program reads

```stata
    generate 'tmp'=exp('1')/'2'
    summarize 'tmp'
    local mean=r(mean)
```

You think that the error may be in the creation of `tmp`. You change the program to read

```stata
    generate 'tmp'=exp('1')/'2'
    pause Just created tmp /* this line is new */
    summarize 'tmp'
    local mean=r(mean)
```

Let’s pretend that your program is named `myprog`; interactively, you now type

```
    . myprog
```

(Any output from your program appears)

That is, `pause` does nothing because pause is off, so `pauses` in your program are ignored. If you turn pause on,

```
    . pause on
    . myprog
```

(Any output from your program appears)

```
pause: Just created tmp
```

```
-> . describe
(output omitted)
```

```
-> . list
(output omitted)
```

407
The “–>” is called the pause-mode prompt. You can give any Stata command. You can examine variables and, if you wish, even change them. If while in pause mode, you wish to terminate execution of your program, you type `BREAK` (in capitals):

```
. myprog
(output omitted)
-> . BREAK
```

The results are the same as if you pressed `Break` while your program was executing. If you press the `Break` key in pause mode (as opposed to typing `BREAK`), however, it means only that the execution of the command you have just given interactively is to be interrupted.

Notes:

- You may put many pauses in your programs.
- By default, pause is off, so the pauses will not do anything. Even so, you should remove the pauses after your program is debugged because each execution of a do-nothing `pause` will slow your program slightly.
- `pause` is implemented as an ado-file; this means that the definitions of local macros in your program are unavailable to you. To see the value of local macros, display them in the `pause` message; for instance,

```
pause Just created tmp, i='i'
```

When the line is executed, you will see something like

```
pause:  Just created tmp, i=1
-> . _
```

- Remember, temporary variables (for example, `tempvar tmp ... gen 'tmp'=...`) are assigned real names, such as `__00424`, by Stata; see `[P] macro`. Thus, in pause mode, you want to examine `__00424` and not `tmp`. Generally, you can determine the real name of your temporary variables from `describe`’s output, but in the example above, it would have been better if `pause` had been invoked with

```
pause Just created tmp, called `tmp', i='i'
```

When the line was executed, you would have seen something like

```
pause: Just created tmp, called __00424, i=1
-> . _
```

- When giving commands that include double quotes, you may occasionally see the error message “type mismatch”, but then the command will work properly:

```
pause: Just created tmp, called __00424, i=1
-> . list if __00424=="male"
type mismatch
(output from request appears as if nothing is wrong)
-> . _
```

[P] program — Define and manipulate programs
[P] more — Pause until key is pressed
[P] trace — Debug Stata programs
[U] 18 Programming Stata
Description

In addition to using ado-files and Mata, you can add new commands to Stata by using the C language by following a set of programming conventions and dynamically linking your compiled library into Stata. The `program` command with the `plugin` option finds plugins and loads (dynamically links) them into Stata.

Syntax

```
program handle, plugin [using(filespec)]
```

Options

- `plugin` specifies that plugins be found and loaded into Stata.
- `using(filespec)` specifies a file, `filespec`, containing the plugin. If you do not specify `using()`, `program` assumes that the file is named `handle.plugin` and can be found along the ado-path (see [U] 17.5 Where does Stata look for ado-files?).

Remarks and examples

Plugins are most useful for methods that require the greatest possible speed and involve heavy looping, recursion, or other computationally demanding approaches. They may also be useful if you have a solution that is already programmed in C.

For complete documentation on plugin programming and loading compiled programs into Stata, see http://www.stata.com/plugins/.

Also see

- [P] automation — Automation
- [P] program — Define and manipulate programs

Mata Reference Manual
These commands are utilities to assist Stata programmers in performing Monte Carlo–type experiments.

*postfile* declares the variable names and the filename of a (new) Stata dataset where results will be saved.

*post* adds a new observation to the declared dataset.

*postclose* declares an end to the posting of observations. After *postclose*, the new dataset contains the posted results and may be loaded using *use*; see [D] *use*.

*postutil dir* lists all open postfiles. *postutil clear* closes all open postfiles.

All five commands manipulate the new dataset without disturbing the data in memory.

If *filename* is specified without an extension, *dta* is assumed.

Declaring variable names and filename of dataset where results will be saved

```
postfile postname newvarlist using filename [, every(#) replace]
```

Adding new observation to declared dataset

```
post postname (exp) (exp) . . (exp)
```

Declaring end to posting of observations

```
postclose postname
```

Listing all open postfiles

```
postutil dir
```

Closing all open postfiles

```
postutil clear
```
Options

every(#) specifies that results be written to disk every #th call to post. post temporarily holds results in memory and periodically opens the Stata dataset being built to append the saved results. every() should typically not be specified, because you are unlikely to choose a value for # that is as efficient as the number post chooses on its own, which is a function of the number of results being written and their storage type.

replace indicates that the file specified may already exist, and if it does, that postfile may erase the file and create a new one.

Remarks and examples

The typical use of the post commands is

```
    tempname memhold
    tempfile results
    ...
    postfile `memhold' ...
    using "'results'"
    ...
    while ... {
        ...
        post `memhold' ...
        ...
    }
    postclose `memhold'
    ...
    use "'results'", clear
    ...
```

Two names are specified with postfile: postname is a name assigned to internal memory buffers, and filename is the name of the file to be created. Subsequent posts and the postclose are followed by postname so that Stata will know to what file they refer.

In our sample, we obtain both names from Stata’s temporary name facility (see [P] macro), although, in some programming situations, you may wish to substitute a hard-coded filename macro. We recommend that postname always be obtained from tempname. This ensures that your program can be nested within any other program and ensures that the memory used by post is freed if anything goes wrong. Using a temporary filename, too, ensures that the file will be erased if the user presses Break. Sometimes, however, you may wish to leave the file of incomplete results behind. That is allowed, but remember that the file is not fully up to date if postclose has not been executed. post buffers results in memory and only periodically updates the file.

Because postfile accepts a newvarlist, storage types may be interspersed, so you could have

```
    postfile `memhold' a b str20 c double(d e f) using "'results'"
```

Note that newvarlist does not allow strL as the variable storage type.

Example 1

We wish to write a program to collect means and variances from 10,000 randomly constructed 100-observation samples of lognormal data and save the results in results.dta. Suppose that we are evaluating the coverage of the 95%, t-based confidence interval when applied to lognormal data. As background, we can obtain a 100-observation lognormal sample by typing

```
    drop _all
    set obs 100
    generate z = exp(rnormal())
```
We can obtain the mean and standard deviation by typing

```
summarize z
```

Moreover, `summarize` stores the sample mean in `r(mean)` and variance in `r(Var)`. It is those two values we wish to collect. Our program is

```
program lnsim
    version 15.0
    tempname sim
    postfile `sim’ mean var using results, replace
    quietly {
        forvalues i = 1/10000 {
            drop _all
            set obs 100
            generate z = exp(rnormal())
            summarize z
            post `sim’ (r(mean)) (r(Var))
        }
    }
    postclose `sim’
end
```

The `postfile` command begins the accumulation of results. `‘sim’` is the name assigned to the internal memory buffers where results will be held; `mean` and `var` are the names to be given to the two variables that will contain the information we collect; and variables will be saved in the file named `results.dta`. Because two variable names were specified on the `postfile` line, two expressions must be specified following `post`. Here the expressions are simply `r(mean)` and `r(Var)`. If we had wanted, however, to store the mean divided by the standard deviation and the standard deviation, we could have typed

```
post `sim’ (r(mean)/r(sd)) (r(sd))
```

Finally, `postclose ‘sim’` concluded the simulation. The dataset `results.dta` is now complete.

```
. set seed 12345
. lnsim
. use results, clear
. describe
Contains data from results.dta
    obs: 10,000
    vars: 2 12 Nov 2016 10:23

Title

_predict — Obtain predictions, residuals, etc., after estimation programming command

Description

_predict is for use by programmers as a subroutine for implementing the predict command for use after estimation; see [R] predict.

Syntax

After regress

_predict [type] newvar [if] [in] [, xb stdp stdf stdr hat cooksdl residuals rstandard rstudent nolabel]

After single-equation (SE) estimators

_predict [type] newvar [if] [in] [, xb stdp nooffset nolabel]

After multiple-equation (ME) estimators

_predict [type] newvar [if] [in] [, xb stdp stddp nooffset nolabel

   equation(ego[, egno])]

Options

xb calculates the linear prediction from the fitted model. That is, all models can be thought of as estimating a set of parameters $b_1, b_2, \ldots, b_k$, and the linear prediction is $\hat{y}_j = b_1 x_{1j} + b_2 x_{2j} + \cdots + b_k x_{kj}$, often written in matrix notation as $\hat{y}_j = x_j b$. For linear regression, the values $\hat{y}_j$ are called the predicted values or, for out-of-sample predictions, the forecast. For logit and probit, for example, $\hat{y}_j$ is called the logit or probit index.

It is important to understand that the $x_{1j}$, $x_{2j}$, $\ldots$, $x_{kj}$ used in the calculation are obtained from the data currently in memory and do not have to correspond to the data on the independent variables used in fitting the model (obtaining the $b_1, b_2, \ldots, b_k$).

stdp calculates the standard error of the prediction after any estimation command. Here the prediction is understood to mean the same thing as the “index”, namely, $x_j b$. The statistic produced by stdp can be thought of as the standard error of the predicted expected value, or mean index, for the observation’s covariate pattern. This is also commonly referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by stdf are always larger than those produced by stdp; see Methods and formulas in [R] predict.
stdr calculates the standard error of the residuals.

hat (or leverage) calculates the diagonal elements of the projection hat matrix.

cooksd calculates the Cook’s D influence statistic (Cook 1977).

residuals calculates the residuals.

rstandard calculates the standardized residuals.

rstudent calculates the Studentized (jackknifed) residuals.

nooffset may be combined with most statistics and specifies that the calculation be made, ignoring any offset or exposure variable specified when the model was fit.

This option is available, even if not documented, for predict after a specific command. If neither the offset(varname) option nor the exposure(varname) option was specified when the model was fit, specifying nooffset does nothing.

nolabel prevents_predict from labeling the newly created variable.

stddp is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ($x_1j b - x_2j b$) between equations 1 and 2 is calculated. Use the equation() option to get the standard error of the difference between other equations.

equation(eqno[ , eqno]) is relevant only when you have previously fit a multiple-equation model. It specifies the equation to which you are referring.

equation() is typically filled in with one eqno—it would be filled in that way with options xb and stddp, for instance. equation(#1) would mean that the calculation is to be made for the first equation, equation(#2) would mean the second, and so on. You could also refer to the equations by their names: equation(income) would refer to the equation named income and equation(hours) to the equation named hours.

If you do not specify equation(), the results are the same as if you specified equation(#1). Other statistics refer to between-equation concepts; stddp is an example. You might then specify equation(#1,#2) or equation(income,hours). When two equations must be specified, equation() is required.

[U] 20 Estimation and postestimation commands
**preserve** — Preserve and restore data

### Description

`preserve` preserves the data, guaranteeing that data will be restored after program termination. `restore` forces a restore of the data now.

### Syntax

**Preserve data**

```
preserve [, changed]
```

**Restore data**

```
restore [, not preserve]
```

### Options

- **changed** instructs `preserve` to preserve only the flag indicating that the data have changed since the last save. Use of this option is strongly discouraged, as explained in the technical note below.
- **not** instructs `restore` to cancel the previous `preserve`.
- **preserve** instructs `restore` to restore the data now, but not to cancel the restoration of the data again at program conclusion. If `preserve` is not specified, the scheduled restoration at program conclusion is canceled.

### Remarks and examples

`preserve` and `restore` deal with the programming problem where the user’s data must be changed to achieve the desired result but, when the program concludes, the programmer wishes to undo the damage done to the data. When `preserve` is issued, the user’s data are preserved. The data in memory remain unchanged. When the program or do-file concludes, the user’s data are automatically restored.

After a `preserve`, the programmer can also instruct Stata to restore the data now with the `restore` command. This is useful when the programmer needs the original data back and knows that no more damage will be done to the data. `restore, preserve` can be used when the programmer needs the data back but plans further damage. `restore, not` can be used when the programmer wishes to cancel the previous `preserve` and to have the data currently in memory returned to the user.
Example 1

preserve is usually used by itself and is used early in the program. Say that a programmer is writing a program to report some statistic, but the statistic cannot be calculated without changing the user’s data. Here changing does not mean merely adding a variable or two; that could be done with temporary variables as described in [P] macro. Changing means that the data really must be changed: observations might be discarded, the contents of existing variables changed, and the like. Although the programmer could just ignore the destruction of the user’s data, the programmer might actually want to use the program herself and knows that she will become exceedingly irritated when she uses it without remembering to first save her data. The programmer wishes to write a programmatically correct, or PC, command. Doing so is not difficult:

```
program myprog
    (code for interpreting — parsing — the user’s request)
    preserve
    (code that destroys the data)
    (code that makes the calculation)
    (code that reports the result)
end
```

To preserve the data, preserve must make a copy of it on disk. Therefore, our programmer smartly performs all the parsing and setup, where errors are likely, before the preserve. Once she gets to the point in the code where the damage must be done, however, she preserves the data. After that, she forgets the problem. Stata handles restoring the user’s data, even if the user presses Break in the middle of the program.

Example 2

Now let’s consider a program that must destroy the user’s data but needs the data back again, and, once the data are recovered, will do no more damage. The outline is

```
program myprog
    (code for interpreting — parsing — the user’s request)
    preserve
    (code that destroys the data)
    (code that makes the first part of the calculation)
    restore
    (code that makes the second part of the calculation)
    (code that reports the result)
end
```

Although there are other ways the programmer could have arranged to save the data and get the data back [snapshot (see [D] snapshot) or save and use with temporary files as described in [P] macro come to mind], this method is better because should the user press Break after the data are damaged but before the data are restored, Stata will handle restoring the data.

Example 3

This time the program must destroy the user’s data, bring the data back and destroy the data again, and finally report its calculation. The outline is
The programmer could also have coded a `restore` on one line and a `preserve` on the next. It would have the same result but would be inefficient, because Stata would then rewrite the data to disk. `restore, preserve` tells Stata to reload the data but to leave the copy on disk for ultimate restoration.

### Example 4

A programmer is writing a program that intends to change the user’s data in memory—the damage the programmer is about to do is not damage at all. Nevertheless, if the user pressed `Break` while the programmer was in the midst of the machinations, what would be left in memory would be useless. The programmatically correct outline is

```plaintext
program myprog
    (code for interpreting — parsing — the user’s request)
    preserve
    (code that destroys the data)
    (code that makes the first part of the calculation)
    restore, preserve
    (code that makes the second part of the calculation)
    (code that reports the result)
end
```

Before undertaking the reformation, the programmer smartly preserves the data. When everything is complete, the programmer cancels the restoration by typing `restore, not`.

### Technical note

`preserve, changed` is best avoided, although it is very fast. `preserve, changed` does not preserve the data; it merely records whether the data have changed since the data were last saved (as mentioned by `describe` and as checked by `exit` and `use` when the user does not also say `clear`) and restores the flag at the conclusion of the program. The programmer must ensure that the data really have not changed.

As long as the programs use temporary variables, as created by `tempvar` (see [P] `macro`), the changed-since-last-saved flag would not be changed anyway—Stata can track such temporary changes to the data that it will, itself, be able to undo. In fact, we cannot think of one use for `preserve, changed`, and included it only to preserve the happiness of our more imaginative users.

[P] `macro` — Macro definition and manipulation
program — Define and manipulate programs

Description

program define defines and manipulates programs. define is required if program_name is any of the words: define, dir, drop, list, or plugin.

program dir lists the names of all the programs stored in memory.

program list lists the contents of the named program or programs. program list _all lists the contents of all programs stored in memory.

program drop eliminates the named program or programs from memory. program drop _all eliminates all programs stored in memory. program drop _allado eliminates all programs stored in memory that were loaded from ado-files. See [U] 17 Ado-files for an explanation of ado-files.

See [U] 18 Programming Stata for a description of programs. The remarks below address only the use of the program dir, program drop, and program list commands.

See [P] trace for information on debugging programs.

See the Combined subject table of contents, which immediately follows the Contents, for a subject summary of the programming commands.

Syntax

Define program

    program [define] program_name [, [nclass|rclass|eclass|sclass]
        byable(recall[, noheader]|oncall) properties(namelist) sort preserve
        plugin]

List names of programs stored in memory

    program dir

Eliminate program from memory

    program drop [ program_name [ program_name [ ... ] ] ] _all | _allado

List contents of program

    program list [ program_name [ program_name [ ... ] ] ] _all
Options

\texttt{nclass} states that the program being defined does not return results in \texttt{r()}, \texttt{e()}, or \texttt{s()}, and is the default.

\texttt{rclass} states that the program being defined returns results in \texttt{r()}. This is done using the \texttt{return} command; see \cite{return}. If the program is not explicitly declared to be \texttt{rclass}, then it may not change or replace results in \texttt{r()}.

\texttt{eclass} states that the program being defined returns results in \texttt{e()} or modifies already existing results in \texttt{e()}. This is done using the \texttt{ereturn} command; see \cite{return} and \cite{ereturn}. If the program is not explicitly declared to be \texttt{eclass}, it may not directly replace or change results in \texttt{e()}.

\texttt{sclass} states that the program being defined returns results in \texttt{s()}. This is done using the \texttt{sreturn} command; see \cite{return}. If the program is not explicitly declared to be \texttt{sclass}, then it may not directly change or replace results in \texttt{s()}, but it still may clear \texttt{s()} by using \texttt{sreturn clear}.

\texttt{byable(recall\texttt{[ }, noheader\texttt{] | onecall})} specifies that the program allow Stata’s \texttt{by varlist:} prefix. There are two styles for writing \texttt{byable} programs: \texttt{byable(recall)} and \texttt{byable(onecall)}. The writing of \texttt{byable} programs is discussed in \cite{byable}.

\texttt{properties(namelist)} states that \texttt{program\_name} has the specified properties. \texttt{namelist} may contain up to 80 characters, including separating spaces. See \cite{program properties}.

\texttt{sortpreserve} states that the program changes the sort order of the data and that Stata is to restore the original order when the program concludes; see \cite{sortpreserve}.

\texttt{plugin} specifies that a plugin (a specially compiled C program) be dynamically loaded and that the plugin define the new command; see \cite{plugin}.

Remarks and examples

The \texttt{program dir} command lists the names of all the programs stored in memory. \texttt{program list} lists contents of the program or programs.

Example 1

When you start Stata, there are no programs stored in memory. If you type \texttt{program dir}, Stata displays an empty list:

\begin{verbatim}
. program dir
.
\end{verbatim}
Later during the session, you might see

```
. program dir
(output omitted)
ado 756 _pred_se
ado 644 logit_p.GenScores
ado 306 logit_p.GetRhs
ado 5296 logit_p
ado 339 predict
(output omitted)
ado 559 logit.Replay
ado 4272 logit.Estimate
ado 827 logit
ado 287 webuse.Query
ado 588 webuse.Set
ado 269 webuse.GetDefault
ado 686 webuse
118187
```

The ado in front indicates that the program was automatically loaded and thus can be automatically dropped should memory become scarce; see [U] 17 Ado-files. The number is the size, in bytes, of the program. The total amount of memory occupied by programs is 114,306 bytes. Notice the logit_p.GetRhs and logit_p.GenScores entries. These programs are defined in the logit_p.ado file and were loaded when logit_p was loaded.

Let’s now create two of our own programs with `program`:

```
. program rng
  1. args n a b
  2. if "'b'"=="" {
    3. display "You must type three arguments: n a b"
    4. exit
    5. }
  6. drop _all
  7. set obs 'n'
  8. generate x = (_n-1)/(_N-1)*('b'-'a')+'a'
  9. end

. program smooth
  1. args v1 v2
  2. confirm variable 'v1'
  3. confirm new variable 'v2'
  4. generate 'v2' = cond(_n==1|_n==_N,'v1',('v1'[_n-1]+v1+v1[_n+1])/3)
  5. end
```
After you type `program`, lines are collected until you type a line with the word `end`. For our purposes, it does not matter what these programs do. If we were now to type `program dir`, we would see

```
. program dir
  286  smooth
  319  rng
(output omitted)
ado  756  _pred_se
ado  644  logit_p.GenScores
ado  306  logit_p.GetRhs
ado  5296  logit_p
ado  339  predict
(output omitted)
ado  559  logit.Replay
ado  4272  logit.Estimate
ado  827  logit
ado  287  webuse.Query
ado  588  webuse.Set
ado  269  webuse.GetDefault
ado  686  webuse
```

We can list a program by using the `program list` command:

```
. program list smooth
smooth:
   1. args v1 v2
   2. confirm variable 'v1'
   3. confirm new variable 'v2'
   4. generate 'v2' = cond(_n==1|_n==_N,'v1','v1'[n]+v1+[n+1])/3
```

If we do not specify the program that we want listed, `program list` lists all the programs stored in memory.
The `program drop` command eliminates programs from memory. Typing `program drop program_name` eliminates `program_name` from memory. Typing `program drop _all` eliminates all programs from memory.

```
. program drop smooth
. program dir
  319    rng
(output omitted)
ado    756    _pred_se
ado    644    logit_p.GenScores
ado    306    logit_p.GetRhs
ado    5296   logit_p
ado    339    predict
(output omitted)
ado    559    logit.Replay
ado    4272   logit.Estimate
ado    827    logit
ado    287    webuse.Query
ado    588    webuse.Set
ado    269    webuse.GetDefault
ado    686    webuse
```

```
118506
```

. program drop _all
. program dir
```

[U] 18 Programming Stata
User-defined programs can have properties associated with them. Some of Stata’s prefix commands—such as svy and stepwise—use these properties for command validation. You can associate program properties with programs by using the `properties()` option of `program`.

```
program [define] command [, properties(namelist) ...]
    // body of the program
end
```

You can retrieve program properties of `command` by using the `properties` extended macro function.

```
  global mname : properties command
  local lclname : properties command
```

**Option**

`properties(namelist)` states that `command` has the specified properties. `namelist` may contain up to 80 characters, including separating spaces.

**Remarks and examples**

Remarks are presented under the following headings:

- Introduction
- Writing programs for use with `nestreg` and `stepwise`
- Writing programs for use with `svy`
- Writing programs for use with `mi`
- Properties for survival-analysis commands
- Properties for exponentiating coefficients
- Putting it all together
- Checking for program properties

**Introduction**

Properties provide a way for a program to indicate to other programs that certain features have been implemented. Suppose that you want to use `stepwise` with the `lr` option so that likelihood-ratio tests are performed in the model-selection process; see [R] `stepwise`. To do that, `stepwise` must know that the estimation command you are using in conjunction with it is a maximum likelihood estimator. If a command declares itself to have the `swml` property, `stepwise` knows that the command can be used with likelihood-ratio tests.

The next few sections discuss properties that are checked by some of Stata’s prefix commands and how to make your own programs work with those prefix commands.
Writing programs for use with `nestreg` and `stepwise`

Some of Stata’s estimation commands can be used with the `nestreg` and `stepwise` prefix commands; see [R] `nestreg` and [R] `stepwise`. For example, the syntax diagram for the `regress` command could be presented as

```
[nestreg, ...:] regress ...
```
or

```
[stepwise, ...:] regress ...
```

In general, the syntax for these prefix commands is

```
prefix_command [, prefix_options] : command depvar (varlist) [ (varlist) ... ]
[ if ] [ in ] [ , options ]
```

where `prefix_command` is either `nestreg` or `stepwise`.

You must follow some additional programming requirements to write programs (ado-files) that can be used with the `nestreg` and `stepwise` prefix commands. Some theoretical requirements must be satisfied to justify using `nestreg` or `stepwise` with a given command.

- `command` must be `eclass` and accept the standard estimation syntax; see [P] `program`, [P] `syntax`, and [P] `mark`.

  ```
  command varlist [ if ] [ in ] [ weight ] [ , options ]
  ```

- `command` must store the model coefficients and ancillary parameters in `e(b)` and the estimation sample size in `e(N)`, and it must identify the estimation subsample in `e(sample)`; see [P] `ereturn`.

- For the likelihood-ratio test, `command` must have property `swml`. For example, the program definition for `poisson` appears as

  ```
  program poisson, ... properties( ... swml ... )
  ```

  `command` must also store the log-likelihood value in `e(ll)` and the model degrees of freedom in `e(df_m)`.

- For the Wald test, `command` must have property `sw` if it does not already have property `swml`. For example, the program definition for `qreg` appears as

  ```
  program qreg, ... properties( ... sw ... )
  ```

  `command` must also store the variance estimates for the coefficients and ancillary parameters in `e(V)`; see [R] `test`.

Writing programs for use with `svy`

Some of Stata’s estimation commands can be used with the `svy` prefix; see [SVY] `svy`. For example, the syntax diagram for the `regress` command could be presented as

```
[svy, ...:] regress ...
```

In general, the syntax for the `svy` prefix is

```
svy [, svy_options] : command varlist [ if ] [ in ] [ , options ]
```
You must follow some additional programming requirements to write programs (ado-files) that can be used with the svy prefix. The extra requirements imposed by the svy prefix command are from the various variance-estimation methods that it uses: vce(bootstrap), vce(brr), vce(jackknife), vce(sdr), and vce(linearized). Each of these variance-estimation methods has theoretical requirements that must be satisfied to justify using them with a given command.

- **command** must be eclass and allow iweights and accept the standard estimation syntax; see [P] program, [P] syntax, and [P] mark.
  
  \`
  command varlist [if] [in] [weight] [ , options ]
  \`

- **command** must store the model coefficients and ancillary parameters in \texttt{e(b)} and the estimation sample size in \texttt{e(N)}, and it must identify the estimation subsample in \texttt{e(sample)}; see [P] ereturn.

- svy’s vce(bootstrap), vce(brr), and vce(sdr) require that **command** have \texttt{svyb} as a property. For example, the program definition for \texttt{regress} appears as
  
  \`
  program regress, ...
  properties(... svyb ...)
  \`

- vce(jackknife) requires that **command** have \texttt{svyj} as a property.

- vce(linearized) has the following requirements:
  
a. **command** must have \texttt{svyr} as a property.

  b. **predict** after **command** must be able to generate scores with the following syntax:

  \`
  predict [type] stub* [if] [in], scores
  \`

  This syntax implies that estimation results with \texttt{k} equations will cause \texttt{predict} to generate \texttt{k} new equation-level score variables. These new equation-level score variables are \texttt{stub1} for the first equation, \texttt{stub2} for the second equation, \ldots, and \texttt{stubk} for the last equation. Actually \texttt{svy} does not strictly require that these new variables be named this way, but this is a good convention to follow.

  The equation-level score variables generated by \texttt{predict} must be of the form that can be used to estimate the variance by using Taylor linearization (otherwise known as the delta method); see [SVY] variance estimation.

  c. **command** must store the model-based variance estimator for the coefficients and ancillary parameters in \texttt{e(V)}; see [SVY] variance estimation.

**Writing programs for use with mi**

Stata’s \texttt{mi} suite of commands provides multiple imputation to provide better estimates of parameters and their standard errors in the presence of missing values; see [MI] intro. Estimation commands intended for use with the \texttt{mi estimate} prefix (see [MI] mi estimate) must have property \texttt{mi}, indicating that the command meets the following requirements:

- The command is eclass.

- The command stores its name in \texttt{e(cmd)}.

- The command stores the model coefficients and ancillary parameters in \texttt{e(b)}, stores the corresponding variance matrix in \texttt{e(V)}, stores the estimation sample size in \texttt{e(N)}, and identifies the estimation subsample in \texttt{e(sample)}. 

The command stores the number of ancillary parameters in \texttt{e(k\_aux)}. This information is used for the model \( F \) test, which is reported by \texttt{mi estimate} when the command stores model degrees of freedom in \texttt{e(df\_m)}.

- If the command employs a small-sample adjustment for tests of coefficients and reports of confidence intervals, the command stores the numerator (residual) degrees of freedom in \texttt{e(df\_r)}.

- Because \texttt{mi estimate} uses its own routines to display the output, to ensure that results display well the command also stores its title in \texttt{e(title)}. \texttt{mi estimate} also uses macros \texttt{e(vcetype)} or \texttt{e(vce)} to label the within-imputation variance, but those macros are usually set automatically by other Stata routines.

**Properties for survival-analysis commands**

Stata’s \texttt{st} suite of commands have the \texttt{st} program property, indicating that they have the following characteristics:

- The command should only be run on data that have been previously \texttt{stset}; see \texttt{[ST] stset}.

- No dependent variable is specified when calling that command. All variables in \texttt{varlist} are regressors. The “dependent” variable is time of failure, handled by \texttt{stset}.

- Weights are not specified with the command but instead obtained from \texttt{stset}.

- If robust or replication-based standard errors are requested, the default level of clustering is according to the \texttt{ID} variable that was \texttt{stset}, if any.

**Properties for exponentiating coefficients**

Stata has several prefix commands—such as \texttt{bootstrap}, \texttt{jackknife}, and \texttt{svy}—that use alternative variance-estimation techniques for existing commands. These prefix commands behave like conventional estimation commands when reporting and saving estimation results. Given the appropriate program properties, these prefix commands can also report exponentiated coefficients. In fact, the property names for the various shortcuts for the \texttt{eform()} option are the same as the option names:

<table>
<thead>
<tr>
<th>option/property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hr</td>
<td>hazard ratio</td>
</tr>
<tr>
<td>nohr</td>
<td>coefficient instead of hazard ratio</td>
</tr>
<tr>
<td>shr</td>
<td>subhazard ratio</td>
</tr>
<tr>
<td>noshr</td>
<td>coefficient instead of subhazard ratio</td>
</tr>
<tr>
<td>irr</td>
<td>incidence-rate ratio</td>
</tr>
<tr>
<td>or</td>
<td>odds ratio</td>
</tr>
<tr>
<td>rrr</td>
<td>relative-risk ratio</td>
</tr>
</tbody>
</table>

For example, the program definition for \texttt{logit} looks something like the following:

```
program logit, ... properties(... or ...)```
Putting it all together

logit can report odds ratios, works with svy, and works with stepwise. The program definition for logit reads

    program logit, ... properties(or svyb svyj svyr swml mi) ...

Checking for program properties

You can use the properties extended macro function to check the properties associated with a program; see [P] macro. For example, the following macro retrieves and displays the program properties for logit.

    . local logitprops : properties logit
    . display "'logitprops'"
    or svyb svyj svyr swml mi bayes

Description

The Project Manager is a tool for organizing and navigating Stata files. It allows you to collect all the files associated with a given project into a single interface where you can have quick access to them without navigating through file dialogs. You can open do-files in the Do-file Editor, use Stata data, and draw saved Stata graphs by double-clicking on the files in the Project Manager. There are no limitations to the kinds of files you can add to a project. If you are using Stata for Mac, you can also open non-Stata documents in their default applications just by double-clicking on the files.

To open the Project Manager, from within the Do-file Editor on Windows and Unix or from within the main menu on Mac, select File > New > Project....

Remarks and examples

Remarks are presented under the following headings:

- Getting started with the Project Manager
- Editing projects
- Properties
- Relative versus absolute paths
- Filtering and searching

Getting started with the Project Manager

When a new project is created in the Project Manager, you are first prompted to save it to disk. A Do-file Editor window is opened when a project is created or opened. Figure 1 shows a new project and an open document in the Do-file Editor.
The left side of the window is the Project Manager. In Windows, the Project Manager pane can be dragged to other positions in the window. The Project Manager shows the contents of a project and their properties. The right side of the window is the Do-file Editor. The Do-file Editor is used to edit Stata text files. See [GSM] 13 Using the Do-file Editor—automating Stata, [GSU] 13 Using the Do-file Editor—automating Stata, or [GSW] 13 Using the Do-file Editor—automating Stata for more information about the Do-file Editor.

The Project Manager shows the groups and files in a project in a hierarchical list called a tree view. Figure 2 shows some of the files and groups in a project we have already created.
The highest level of the hierarchy in the Project Manager is the project. It can contain groups and files. A group appears in the Project Manager as a folder and is a container for other groups and files. It is not a reference to a directory on disk. Although you can organize your project in the Project Manager to reflect the organization of files on disk, moving files into and out of groups does not affect the content of the directory on disk, and moving files into and out of directories on disk does not affect the content of the groups in the Project Manager. A file in the Project Manager is a reference to a file on disk.

Clicking on the disclosure button next to a project or group icon reveals or hides items in the project. Groups and files are displayed alphabetically in the Project Manager, and groups are always displayed before files. If a file in a project does not exist on disk, its filename will be displayed in red.

Below the tree view is the Properties pane, which shows the properties for the current selection. From the Properties pane, you can rename groups and files, change a file’s relative reference location on disk to the project, or change a file’s reference to a different file on disk.

On Windows, there is a Search field above the tree view that allows you to filter or search for files in a project.

On Mac and Unix, the bottom of the Project Manager contains tools for adding or removing groups and files. On the Mac, there is a single button that displays a menu of possible actions such as adding and removing groups and files. On Unix, there are separate buttons for adding and removing groups and files. Next to the buttons is a Search field that allows you to filter or search for files in a project.
Editing projects

When starting a new project, we recommend that you create a new directory on disk and store the project file and the files referenced by the project in the new directory. If you already have a directory of existing Stata files, save the new project in the directory.

You can add files to a project by dragging the files from disk to the Project Manager or by right-clicking on an item in the Project Manager and selecting Add Files to "name".... When a directory on disk is added to a project, its organization on disk at that moment is reflected in the project. Groups and files can be moved into and out of groups using drag and drop.

To create a new group, select the location in the Project Manager where you want the group added, right-click, and select Add New Group. You can drag files into the group, and you can drag the group to a new location in the Project Manager. You can also create a new group from multiple files by selecting the files, right-clicking on the files, and selecting Add New Group from Selection. A new group will be created, and the selected files will be moved into the group. You can change the name of a group by selecting it and entering a new name in the Name edit field.

To remove files from a project, select the files in the Project Manager, right-click on the files, and select Remove from Project. Removing a file from a project does not delete the file on disk. When removing a file from a project on the Mac, you can choose to also move the file on disk to the Trash folder.

Properties

Below the Project Manager’s tree view is the Properties pane. The Properties pane shows the filename and path for the currently selected item. Figure 3 shows the properties of a do-file that is currently selected.

![Figure 3. Properties of a selected do-file](image)

The Name edit field displays the filename for the currently selected group or file. It can be used to rename groups and files. If a file is renamed in the project, the file on disk is also renamed. However, renaming a file on disk does not rename the file in the project and will cause the file to display in red because it cannot be found.

Below the Name edit field is the Type label. This displays whether the selected item is a project, group, or document.

Below the Type edit field is the Location pop-up menu. It specifies whether a file’s path is absolute or relative to the project file. Files that are added to a project have their location set to Relative to Project by default unless they do not share a common parent directory with the project file. For example, files that are added from a hard drive different from that of the project file will have their location set to absolute. You can change a file’s location setting by selecting the appropriate location setting from the Location pop-up menu.
The relative path location setting denotes the file’s path in relation to the location of the project file on disk. If a file is set to use a relative path, the relative path is displayed below the pop-up menu. Relative paths make projects more portable because you can simply copy a project and all the files it references to another computer. The file references will stay intact.

The absolute path location setting denotes that the file is at a fixed location on disk. A file in a project that uses an absolute path will not be affected if its project file is moved. This can be useful for referencing a Stata dataset that is in a fixed location on disk and is referenced by multiple projects.

Below the Location pop-up menu is the Relink button, which allows you to change a file’s reference to a different file on disk. It is useful for resolving files that cannot be found. For example, if you rename a file on disk, the project that references it can no longer find the file. You can use the Relink button to change a file’s reference to the renamed file.

The full path of a selected file is displayed at the bottom of the Properties pane. The full path is always displayed as an absolute path regardless of a file’s location setting. On Mac, there is a button next to the Full Path text field. Pressing this button will open the file’s parent directory on the desktop.

Relative versus absolute paths

A relative path denotes a file’s path in relation to the location of the project file on disk. An absolute path denotes a file’s path at a fixed location on disk. A disadvantage of using absolute paths is that it makes a project less portable and more difficult to transfer to another computer. In most cases, you want to use relative paths in your project. There are some situations, however, where you might want to use absolute paths. For example, you have an extremely large dataset that is used by different projects, and you do not want to have multiple copies of the dataset taking up disk space. Another example would be a do-file that is used by different projects that you modify often; keeping multiple copies of the do-file in sync is difficult.

Relative paths require that projects and their files maintain their relative locations on disk. We recommend that you create a directory in which to store a project and all of its files and use relative paths in the project as much as possible. You can then copy the directory to another computer, including Mac and Unix, and the project can be used as is. By default, the Project Manager uses relative paths when a file is added to a project. However, it is up to users to use relative paths in their do-files. The Project Manager is a tool for organizing Stata files, but it cannot ensure that file references in do-files are maintained, too.

Filtering and searching

The Project Manager can use a filter to display only those files that match a filter text. Click on the button in the Search field below the Properties pane and select Filter if it is not already selected. As you enter text, the Project Manager will update and display only those files and groups and parent groups that contain the text. Figure 4, for example, shows a project filtered to show only do-files (.do).
You can move, rename, remove, or add a file or group while a project is filtered. If a file is added or renamed while a project is filtered, the file will not appear in the filtered list if its filename does not match the filter text. To stop filtering a project, clear the text in the Search field.

You can also search for a filename in a project. Click on the button in the Search field, and select Search if it is not already selected. After entering text in the Search field, press the Enter key to begin the search. If a filename matches the search text, the filename is selected and scrolled into view. Pressing the Enter key again will search for a matching filename again. If there is no matching filename beyond the current selection, the search is resumed from the top of the project. Holding down the Shift key while pressing the Enter key will search in reverse.

[R] doedit — Edit do-files and other text files
Description

putdocx writes paragraphs, images, and tables to an Office Open XML file (.docx). It may also be used to format each object added. This allows you to automate exporting and formatting of, for example, Stata estimation results and also to generate various reports based on those results. The generated file is compatible with Microsoft Word 2007 and later.

Quick start

Create a document in memory on which subsequent contents are added

    putdocx begin

Declare a paragraph to be added to the document and center the paragraph

    putdocx paragraph, halign(center)

Append the text “This is paragraph text” to the paragraph declared above and format the text as bold

    putdocx text ("This is paragraph text"), bold

Add a table named tbl1 with three rows and four columns to the document

    putdocx table tbl1 = (3,4)

Set the content of the cell on the first row and second column of the above table as “Cell 2” and align the text to the right

    putdocx table tbl1(1,2) = ("Cell 2"), halign(right)

Add a table named tbl2 with variable names and estimated coefficients after `regress`, and format coefficients with two decimal places

    matrix b = e(b)'
    putdocx table tbl2 = matrix(b), rownames nformat(%7.2f)

Add a PNG image saved as myimg to the document

    putdocx paragraph
    putdocx image myimg.png

Save the document in memory to disk as myfile.docx

    putdocx save myfile.docx

Append the contents of filename2.docx and filename3.docx to the end of the contents in filename1.docx

    putdocx append filename1 filename2 filename3

As above, but save the merged contents in a file named filename4.docx

    putdocx append filename1 filename2 filename3, saving(filename4)
Syntax

Create document for export

```plaintext
putdocx begin [, pagesize(psize) landscape font(fspec)]
```

Add paragraph to document

```plaintext
putdocx paragraph [, paragraph_options]
```

Add text to paragraph

```plaintext
putdocx text (exp) [, text_options]
```

Add image to paragraph

```plaintext
putdocx image filename [, image_options]
```

Add table to document

```plaintext
putdocx table tablename = (nrows, ncols) [, table_options]
putdocx table tablename = data(varlist) [if] [in] [, varnames obsno table_options]
putdocx table tablename = matrix(matname) [, nformat(%)fmt] rownames colnames table_options
putdocx table tablename = mata(matname) [, nformat(%)fmt] table_options
putdocx table tablename = returnset [, table_options]
```

Customize rows and columns

```plaintext
putdocx table tablename(i,.), row_col_options
putdocx table tablename(.,j), row_col_options
```

Add and format contents of table

```plaintext
putdocx table tablename(i,j) = (exp) [, cell_options]
putdocx table tablename(i,j) = image(filename) [, image_options cell_options]
putdocx table tablename(i,j) = table(mem_tablename) [, cell_options]
putdocx table tablename(i,j), cell_options
```

Add page break to document

```plaintext
putdocx pagebreak
```
Describe current document

    putdocx describe

Describe table

    putdocx describe tablename

Save document

    putdocx save filename [, replace | append]

Merge documents

    putdocx append filename1 filename2 [filename3 [...]]
    [
      , saving(filename [, replace])
    ]

tablename specifies the name of a new table. The name must be a valid name according to Stata’s naming conventions; see [U] 11.3 Naming conventions.

nrows and ncols specify the number of rows and the number of columns in the new table.

matname specifies the name of an existing Stata matrix or Mata matrix.

returnset specifies a group of Stata return values and may be one of the following:

<table>
<thead>
<tr>
<th>returnset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>escalars</td>
<td>All ereturned scalars</td>
</tr>
<tr>
<td>rscalars</td>
<td>All returned scalars</td>
</tr>
<tr>
<td>emacros</td>
<td>All ereturned macros</td>
</tr>
<tr>
<td>rmacros</td>
<td>All returned macros</td>
</tr>
<tr>
<td>ematrices</td>
<td>All ereturned matrices</td>
</tr>
<tr>
<td>rmatrices</td>
<td>All returned matrices</td>
</tr>
<tr>
<td>e*</td>
<td>All ereturned scalars, macros, and matrices</td>
</tr>
<tr>
<td>r*</td>
<td>All returned scalars, macros, and matrices</td>
</tr>
</tbody>
</table>

mem_tablename specifies the name of a previously created table.

paragraph_options

<table>
<thead>
<tr>
<th>paragraph_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>style(pstyle)</td>
<td>set paragraph text with specific style</td>
</tr>
<tr>
<td>font(fspec)</td>
<td>set font, font size, and font color</td>
</tr>
<tr>
<td>halign(hvalue)</td>
<td>set paragraph alignment</td>
</tr>
<tr>
<td>valign(vvalue)</td>
<td>set vertical alignment of characters on each line</td>
</tr>
<tr>
<td>indent(indentype, #unit)</td>
<td>set paragraph indentation</td>
</tr>
<tr>
<td>spacing(position, #unit)</td>
<td>set spacing between lines of text</td>
</tr>
<tr>
<td>shading(sspec)</td>
<td>set background color, foreground color, and fill pattern</td>
</tr>
<tr>
<td>text_options</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td><code>nformat(\%fmt)</code></td>
<td>specify numeric format for new text</td>
</tr>
<tr>
<td><code>font(fspec)</code></td>
<td>set font, font size, and font color</td>
</tr>
<tr>
<td><code>bold</code></td>
<td>format new text as bold</td>
</tr>
<tr>
<td><code>italic</code></td>
<td>format new text as italic</td>
</tr>
<tr>
<td>`script(sub</td>
<td>super)`</td>
</tr>
<tr>
<td><code>underline[ (upattern)]</code></td>
<td>underline text using specified pattern</td>
</tr>
<tr>
<td><code>strikeout</code></td>
<td>strikeout new text</td>
</tr>
<tr>
<td><code>shading(sspec)</code></td>
<td>set background color, foreground color, and fill pattern</td>
</tr>
<tr>
<td><code>linebreak</code></td>
<td>add a line break after new text</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>image_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>width(#[unit])</code></td>
<td>set image width</td>
</tr>
<tr>
<td><code>height(#[unit])</code></td>
<td>set image height</td>
</tr>
<tr>
<td><code>link</code></td>
<td>insert link to image file</td>
</tr>
<tr>
<td><code>linebreak</code></td>
<td>add a line break after new image; not available with putdocx table</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>table_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<tr>
<td>shading(ss)</td>
<td>set background color, foreground color, and fill pattern</td>
</tr>
</tbody>
</table>

fs is:

\[\text{fontname} [ , \text{size} [ , \text{color} ] ]\]

fontname may be any valid font installed on the user’s computer. If fontname includes spaces, then it must be enclosed in double quotes.

size is a numeric value that represents font size measured in points. The default is 11.

color sets the text color.

ss is:

\[\text{bgcolor} [ , \text{fgcolor} [ , \text{fpattern} ] ]\]

bgcolor specifies the background color.

fgcolor specifies the foreground color. The default foreground color is black.

fpattern specifies the fill pattern. The most common fill patterns are solid for a solid color (determined by fgcolor), pct25 for 25% gray scale, pct50 for 50% gray scale, and pct75 for 75% gray scale. A complete list of fill patterns is shown in the Appendix.

bs is:

\[\text{bordername} [ , \text{bpattern} [ , \text{bcolor} ] ]\]

bordername specifies the location of the border.

bpattern is a keyword specifying the look of the border. The most common patterns are single, dashed, dotted, and double. The default is single. For a complete list of border patterns, see the Appendix. To remove an existing border, specify nil as the bpattern.

bcolor specifies the border color.

unit may be in (inch), pt (point), cm (centimeter), or twip (twentieth of a point). An inch is equivalent to 72 points, 2.54 centimeters, or 1440 twips. The default is in.

color, bgcolor, fgcolor, and bcolor may be one of the colors listed in the table of colors in the Appendix; a valid RGB value in the form ### ### ###, for example, 171 248 103; or a valid RRGGBB hex value in the form ######, for example, ABF867.
putdocx paragraph adds a new paragraph to the active document. The newly created paragraph becomes the active paragraph. All subsequent text or images will be appended to the active paragraph.

putdocx text (exp) adds content to the paragraph created by putdocx paragraph. exp may be a valid Stata expression (see [U] 13 Functions and expressions) or a normal string.

putdocx image filename embeds a portable network graphics (.png), JPEG (.jpg), enhanced metafile (.emf), or tagged image file format (.tif) file in the active paragraph. filename is the path to the image file. It may be either the full path or the relative path from the current working directory.

Adding an image is not supported on console Stata for Mac.

putdocx table tablename creates a new table that can be identified by its assigned name, tablename, for future modifications. Tables may be created in several ways:

\((nrows, ncols)\) creates an empty table with nrows rows and ncols columns. Microsoft Word 2007/2010 allows a maximum of 63 columns in a table.

\(\text{data(varlist)} \ [\text{if} \] \ [\text{in}] \ [\text{, varnames obsno} \]\) adds the current Stata dataset in memory as a table to the active document. varlist contains a list of the variable names from the current dataset in memory. If the varnames option is specified, the first row of the table is filled with variable names. If obsno is specified, the first column of the table is filled with observation numbers. if and in may be used to restrict the data to be added to the table.

\(\text{matrix(matname)} \ [\text{, nformat(\%fmt)} \text{ rownames colnames}]\) adds a matrix called matname as a table to the active document. The elements of the matrix are formatted using \%fmt. If nformat() is not specified, then \%12.0g is used. If the rownames option is specified, the first column of the table is filled with matrix rownames. If the colnames option is specified, the first row of the table is filled with matrix colnames.

\(\text{mata(matname)} \ [\text{, nformat(\%fmt)}\]\) adds a Mata matrix called matname as a table to the active document. The elements of the matrix are formatted using \%fmt. If nformat() is not specified, then \%12.0g is used.

returnset exports a group of Stata return values to a table in the active document. It is intended primarily for use by programmers and by those who want to do further processing of their exported results in the active document.

putdocx table tablename(i, j) modifies the content and styles of the cell on the \(i\)th row and \(j\)th column in table tablename. The cell content may be a valid Stata expression, an image with supported format, a previously created table identified by mem_tablename, or combinations of those three elements by using option append.
Options

Options are presented under the following headings:

- **Options for putdocx begin**
- **Options for putdocx paragraph**
- **Options for putdocx text**
- **Options for putdocx image**
- **Options for putdocx table**
  - table_options
  - row_col_options
  - cell_options
  - image_options
- **Options for putdocx save**
- **Option for putdocx append**

**Options for putdocx begin**

pagesize(*psize*) sets the page size of the document. *psize* may be letter, legal, A3, A4, or B4JIS. The default is pagesize(letter).

landscape changes the document orientation from portrait to landscape.

**font(*fontname [, size [, color]]*)** sets the font, font size, and font color for the document. Note that the font size and font color may be specified individually without specifying *fontname*. Use **font("", size)*** to specify font size only. Use **font("", "", color)** to specify font color only. For both cases, the default font will be used.

**Options for putdocx paragraph**

style(*pstyle*) specifies that the text in the paragraph be formatted with style *pstyle*. Common values for *pstyle* are Title, Subtitle, and Heading1. See the complete list of paragraph styles in the Appendix.

**font(*fontname [, size [, color]]*)** sets the font, font size, and font color for the paragraph. Note that the font size and font color may be specified individually without specifying *fontname*. Use **font("", size)*** to specify font size only. Use **font("", "", color)** to specify font color only. For both cases, the default font will be used.

Specifying **font()** with **putdocx paragraph** overrides font settings specified with **putdocx begin**.

**halign(*hvalue*)** sets the horizontal alignment of the characters within the paragraph. *hvalue* may be left, right, center, both, or distribute. distribute and both justify text between the left and right margins equally, but distribute also changes the spacing between words and characters. The default is halign(left).

**valign(*vvalue*)** sets the vertical alignment of the characters on each line when the paragraph contains characters of varying size. *vvalue* may be auto, baseline, bottom, center, or top. The default is valign(baseline).

**indent(*indenttype, [# unit]*)** specifies that the paragraph be indented by # units. *indenttype* may be left, right, hanging, or para. left and right indent # units from the left or the right, respectively. hanging uses hanging indentation and indents lines after the first line by # inches unless another unit is specified. para uses standard paragraph indentation and indents the first line by # inches unless another unit is specified. This option may be specified multiple times in a single command to accommodate different indentation settings. If both indent(hanging) and indent(para) are specified, only indent(hanging) is used.
spacing(position, # [unit]) sets the spacing between lines of text. position may be before, after, or line. before specifies the space before the first line of the current paragraph, after specifies the space after the last line of the current paragraph, and line specifies the space between lines within the current paragraph. This option may be specified multiple times in a single command to accommodate different spacing settings.

shading(bgcolor [, fgcolor [, fpattern]]) sets the background color, foreground color, and fill pattern for the paragraph.

Options for putdocx text

nformat(%, fmt) specifies the numeric format of the text when the content of the new text appended to the paragraph is a numeric value. This setting has no effect when the content is a string.

font(fontname [, size [, color]]) sets the font, font size, and font color for the new text. Note that the font size and font color may be specified individually without specifying fontname. Use font("", size) to specify font size only. Use font("", "", color) to specify font color only. For both cases, the default font will be used.

Specifying font() with putdocx text overrides all other font settings, including those specified with putdocx begin and putdocx paragraph.

bold specifies that the new text be formatted as bold.

italic specifies that the new text be formatted as italic.

underline( [upattern]) specifies that the new text be underlined and optionally specifies the format of the line. By default, a single underline is used. The optional upattern may be any of the patterns listed in the Appendix. The most common patterns are double, dash, and none.

strikeout specifies that the text have a strikeout mark.

script(sub | super) changes the script style of the text. script(sub) makes the text a subscript. script(super) makes the text a superscript.

shading(bgcolor [, fgcolor [, fpattern]]) sets the background color, foreground color, and fill pattern for the new text.

Specifying shading() with putdocx text overrides shading specifications from putdocx paragraph.

linebreak specifies that a line break be added after the new text. This option may be specified multiple times to add multiple line breaks after the new text.

Options for putdocx image

width(# [unit]) sets the width of the image. If the width is larger than the body width of the document, then the body width is used. If width() is not specified, then the default size is used; the default is determined by the image information and the body width of the document.

height(# [unit]) sets the height of the image. If height() is not specified, then the height of the image is determined by the width and the aspect ratio of the image.

link specifies that a link to the image filename be inserted into the document. If the image is linked, then the referenced file must be present so that the document can display the image.

linebreak specifies that a line break be added after the new image. This option may be specified multiple times to add multiple line breaks after the new image.
Options for putdocx table

**table_options**

- **memtable** specifies that the table be created and held in memory instead of being added to the active document. By default, the table is added to the document immediately after it is created. This option is useful if the table is intended to be added to a cell of another table or to be used multiple times later.

- **halign(hvalue)** sets the horizontal alignment of the table within the page. *hvalue* may be left, right, or center. The default is halign(left).

- **indent(#[unit])** specifies the table indentation from the left margin of the current document.

- **layout(layouttype)** adjusts the column width of the table. *layouttype* may be fixed, autofitwindow, or autofitcontents. fixed means the width is the same for all columns in the table. When autofitwindow is specified, the column width automatically resizes to fit the window. When autofitcontents is specified, the table width is determined by the overall table layout algorithm, which automatically resizes the column width to fit the contents. The default is layout(autofitwindow).

- **width(#[unit]|\%])** sets the table width. # may be an absolute width or a percent of the default table width, which is determined by the page width of the document. For example, width(50\%) sets the table width to 50\% of the default table width. The default is width(100\%).

- **cellmargin(cmarg, #[unit])** sets the cell margins for table cells. *cmarg* may be top, bottom, left, or right. This option may be specified multiple times in a single command to accommodate different margin settings.

- **cellspacing(#[unit])** sets the spacing between adjacent cells and the edges of the table.

- **border(bordername [, bpattern [, bcolor]]** sets the pattern and color for the specified border of the table or a cell. This option may be specified multiple times in a single command to accommodate different border settings.

  For a table or cell, *bordername* may be start, end, top, bottom, or all. For a table, *bordername* may also be insideH, the inside horizontal edges border, or insideV, the inside vertical edges border.

  Specifying border(start) adds a single border to the leading edge of the table or cell. Similarly, specifying border(end), border(top), or border(bottom) adds a single border to the trailing edge, top, or bottom of the table or cell. border(all) applies the specified pattern and color to all borders, including the inside edges when specified for a table.

- **headerrow(#)** sets the top # rows to be repeated as header rows at the top of each page on which the table is displayed. This setting has a visible effect only when the table crosses multiple pages.

- **varnames** specifies that the variable names be included as the first row in the table when the table is created using the dataset in memory. By default, only the data values are added to the table.

- **obsno** specifies that the observation numbers be included as the first column in the table when the table is created using the dataset in memory. By default, only the data values are added to the table.

- **nformat(%fmt)** specifies the numeric format to be applied to the source values when creating the table from a Stata or Mata matrix. The default is nformat(%12.0g).

- **rownames** specifies that the row names of the Stata matrix be included as the first column in the table. By default, only the matrix values are added to the table.

- **colnames** specifies that the column names of the Stata matrix be included as the first row in the table. By default, only the matrix values are added to the table.
row_col_options

nosplit specifies that row \( i \) not split across pages. When displaying a table row, it is possible that a page break will fall within the contents of a cell on the row, causing the contents of that cell to be displayed across two pages. \texttt{nosplit} prevents this behavior. If the entire row cannot fit on the current page, the row will be moved to the start of the next page.

\texttt{addrows(# \{before|after\})} adds \# rows to the current table before or after row \( i \). If \texttt{before} is specified, the rows are added before the specified row. By default, rows are added after the specified row.

\texttt{addcols(# \{before|after\})} adds \# columns to the current table to the right or the left of column \( j \). If \texttt{before} is specified, the columns are added to the left of the specified column. By default, the columns are added after, or to the right of, the specified column.

drop deletes row \( i \) or column \( j \) from the table.

cell_options

append specifies that the new content for the cell be appended to the current content of the cell. If \texttt{append} is not specified, then the current content of the cell is replaced by the new content.

\texttt{font(fontname \{size|color\})} sets the font, font size, and font color for the text within the cell. Note that the font size and font color may be specified individually without specifying \texttt{fontname}. Use \texttt{font("", size)} to specify font size only. Use \texttt{font("", ", color)} to specify font color only. For both cases, the default font will be used.

\texttt{bold} specifies that the text be formatted as bold.

\texttt{italic} specifies that the text be formatted as italic.

\texttt{underline([upattern])} specifies that the cell be underlined and optionally specifies the format of the line. By default, a single underline is used. The optional \texttt{upattern} may be any of the patterns listed in the Appendix. The most common patterns are double, dash, and none.

\texttt{strikeout} specifies that the text have a strikeout mark.

\texttt{halign(hvalue)} sets the horizontal alignment of the cell. \texttt{hvalue} may be left, right, or center. The default is \texttt{halign(left)}.

\texttt{valign(vvalue)} sets the vertical alignment of the cell. \texttt{vvalue} may be top, bottom, or center. The default is \texttt{valign(top)}.

\texttt{rowspan(#)} sets the specified cell to span vertically \# cells downward. If the span exceeds the total number of rows in the table, the span stops at the last row.

\texttt{colspan(#)} sets the specified cell to span horizontally \# cells to the right. If the span exceeds the total number of columns in the table, the span stops at the last column.

\texttt{span(#1, #2)} sets the specified cell to span \#1 cells downward and span \#2 cells to the right.

\texttt{shading(bgcolor \{fgcolor \{fpattern\}\})} sets the background color, foreground color, and fill pattern for the cell.
image_options

width(#\leftunit) sets the width of the image. If the width is larger than the width of the cell, then the width is used. If width() is not specified, then the default size is used; the default is determined by the image information and the width of the cell.

height(#\leftunit) sets the height of the image. If height() is not specified, then the height of the image is determined by the width and the aspect ratio of the image.

link specifies that a link to the image filename be inserted into the document. If the image is linked, then the referenced file must be present so that the document can display the image.

Options for putdocx save

replace specifies to overwrite filename, if it exists, by the contents of the document in memory.
append specifies to append the contents of the document in memory to the end of filename.

Option for putdocx append

saving(filename [, replace]) specifies to append the contents of the existing document filename2 to the end of filename1 and then write the result to the new document filename. If filename already exists, it can be overwritten by specifying replace. By default, filename1 is replaced with the document created by appending content from filename2.

If more than two files are specified, the contents are appended in the order in which they are listed. For example, filename2 is appended to filename1, filename3 is appended to the result of the first append, and so forth.

Remarks and examples

The putdocx command is a suite of commands used to write paragraphs, images, and tables to an Office Open XML file (.docx). It may also be used to format each object added. This allows you to automate the exporting and formatting of, for example, Stata graphs and estimation results, and also to generate various reports based on those elements. Moreover, it can be used to append those elements to an existing .docx file or to merge multiple .docx files. Hence, it provides a convenient way to interact Stata results with a .docx file.

putdocx generates files compatible with Microsoft Word 2007 and later. It is supported on Windows, Mac, and Linux.

Before we can write to a .docx file using putdocx, we need to create a .docx document in memory. We do this using the putdocx begin command.

. putdocx begin

Once the document is created, other objects such as paragraphs and tables may be added to it. By default, the document created uses the letter pagesize, and its layout is set to portrait. Those properties may be overwritten by specifying corresponding document options. Some other properties may also be customized; see Options for putdocx begin in Options.

After we are done editing the document, we can save it to disk.

. putdocx save example.docx
Note that either the replace or the append option is required if example.docx already exists in the saving directory. If replace is specified, then all the contents in example.docx will be overwritten. If append is specified, then all the contents of the active document in memory will be appended to the end of example.docx.

Remaining remarks are presented under the following headings:

- Add a paragraph
- Add text to paragraph
- Add an image to paragraph
- Add a table
- Export data
- Export estimation results
- Advanced uses

**Add a paragraph**

Before you can add text or an image to the paragraph, you must first begin a new paragraph by using `putdocx paragraph`. You can control the formatting for the whole paragraph, such as font properties and alignment, with options for `putdocx paragraph`. See *Options for putdocx paragraph* for paragraph formatting options. The current paragraph remains active until you add a new paragraph or add a table.

**Add text to paragraph**

Once the new paragraph is created, you add text to it by using `putdocx text`. The new text is appended to the text or the image that has already been added to the paragraph. This text can also be formatted individually. See *Options for putdocx text* for text formatting options.

**Example 1: Add a paragraph and format the text**

Suppose we want to write a description of auto.dta to example.docx. Our description includes the number of automobiles and the maximum miles per gallon (MPG) among all the automobiles. We can create a paragraph containing that information by using `putdocx paragraph`.

To start, we use the `summarize` command to get descriptive statistics for the mpg variable. After that, we can use the returned results from `summarize` in the text that we write. The returned results \( r(N) \) and \( r(max) \) store the number of automobiles and the maximum MPG among those automobiles, respectively.

```
. use http://www.stata-press.com/data/r15/auto
   (1978 Automobile Data)
. summarize mpg

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
</tbody>
</table>
```

Note: The example data file `auto.dta` is available from Stata Press. Please visit the Stata Press website for more information.
Now, we specify the command to create our document. We then add a new paragraph to the active
document and append text to it. The content of each `putdocx text` command may be a valid Stata
expression (see [U] 13 Functions and expressions) or a normal string. `putdocx text` can be used
to break long sentences into pieces, and each piece in the paragraph can be customized to have a
different style. Here, `r(max)` is formatted as bold.

```
. putdocx begin
. putdocx paragraph
. putdocx text ("In this dataset, there are ‘r(N)’")
. putdocx text (" models of automobiles. The maximum MPG among them is ")
. putdocx text (r(max)), bold
. putdocx text (".
")
```

This adds text to the document that looks like this:

```
In this dataset, there are 74 models of automobiles. The maximum MPG among them is 41.
```

**Add an image to paragraph**

You can add any existing `.png`, `.jpg`, `.emf`, and `.tif` image files to a `.docx` file with `putdocx`
image. For example, you could include a company logo. You can also add graphs from Stata output.
Because Stata graphs use the `.gph` extension, you must use `graph export` to convert the Stata graph
to one of the supported image formats; see [G-2] `graph export`.

By default, images are embedded in the file. If the image is embedded, it becomes a part of the
document and has no further relationship with the original image on the disk. You can instead link
the image by specifying the `link` option. Using linked images means that if the image file on the
disk is updated, then the linked image in the document will reflect the change.
If you are adding the image after text and you want the paragraph that contains the image to have the same format as the active paragraph, you can insert the image with no additional step. However, if you want to change the formatting or if there is no active paragraph, you must create one using \texttt{putdocx paragraph}. Note that you do not need to declare a new paragraph to insert an image into the cell of a table.

\textbf{Example 2: Export a Stata graph}

We may want to add a scatterplot showing how mileage (\texttt{mpg}) correlates with price (\texttt{price}) of cars. We can use the \texttt{scatter} command and then \texttt{graph export} to create a .\texttt{png} file.

\begin{verbatim}
. scatter mpg price

. graph export auto.png
(file auto.png written in PNG format)
\end{verbatim}

Next, we use \texttt{putdocx image} to add the .\texttt{png} file to the document. Because our active paragraph is left aligned and we want our image to be centered, we declare a new paragraph and specify the \texttt{halign()} option.

\begin{verbatim}
. putdocx paragraph, halign(center)
. putdocx image auto.png
\end{verbatim}

\textbf{Add a table}

\texttt{putdocx table} is used to add a table to the document. A valid table name is required to declare a table. The table name is used later as a reference to customize the table and the cells.
Exporting the data in memory is useful when you want to make a table in the .docx file using content from your dataset. The if or in qualifier may be applied to export only those observations that meet the specified condition or are in the specified range (or both, if both if and in are specified).

Example 3: Export table of summary statistics

Suppose we want to export summary statistics, such as the number of automobiles, the maximum and minimum MPG, and the average MPG, that have been calculated separately for foreign and domestic automobiles. To start, we use the `statsby` command to collect the above statistics for each group. Because `statsby` creates a new dataset that overwrites the dataset in memory, we need to preserve the dataset and then restore it after we have finished exporting the data.

```
preserve
.statsby Total=r(N) Average=r(mean) Max=r(max) Min=r(min), by(foreign):
> summarize mpg
(running summarize on estimation sample)
command: summarize mpg
Total: r(N)
Average: r(mean)
Max: r(max)
Min: r(min)
by: foreign
Statsby groups
```

Then, we export the data in memory as a table by specifying in `data()` the variable names Origin, Total, Average, Max, and Min. In this case, we use the table name `tbl1`. The order of the variable names in the list determines the column order in the table.

```
.rename foreign Origin
.putdocx table tbl1 = data("Origin Total Average Max Min"), varnames
> border(start, nil) border(insideV, nil) border(end, nil)
```

By default, the exported table includes single borders around all cells. We use the `border()` option to remove all vertical borders from the table. We can apply additional formatting to individual cells or ranges of cells; see example 4.

Example 4: Format table

The cells in the table that we created in example 3 can be further customized. For example, we can reset the contents, set the text alignment, modify the borders, and so forth. Here, we set the horizontal text of the cells on the second through the fifth columns to be right aligned instead of the default left alignment.

```
.forvalues row=1/3 {
 2. forvalues col=2/5 {
 3.   putdocx table tbl1(‘row’,‘col’), halign(right)
 4. }
 5. }
```
Our formatted tbl1 looks like this:

![Table Image]

Afterward, we restore the dataset.

```
. restore
```

**Export estimation results**

One of the primary uses of `putdocx table` is to export estimation results. Suppose we fit a linear regression model of `mpg` as a function of the car’s gear ratio (`gear_ratio`), turning radius (`turn`), and whether the car is of foreign origin (`foreign`) using `regress`. We want to add selected regression results to the document.

```
. regress mpg gear_ratio turn foreign, noheader
```

```
Coef. Std. Err. t P>|t| [95% Conf. Interval]
gear_ratio 4.855506 1.522481 3.19 0.002 1.819013 7.891999
turn -0.8364698 .1440204 -5.81 0.000 -1.123709 -.5492302
foreign -3.503218 1.433526 -2.44 0.017 -6.362296 -.6441404
_cons 40.865 8.692731 4.70 0.000 23.52789 58.2021
```

```
. return list
scalars: r(level) = 95
matrices: r(table) : 9 x 4
```

```
. matrix list r(table)
```

```
    gear_ratio   turn   foreign    _cons
  b   4.8555057  -.83646975  -3.5032183   40.864996
  se  1.5224812   .14402036   1.4335262   8.6927313
  t   3.1892057  -5.8079965  -2.4437769   4.7010537
 pvalue .0021348  1.704e-07  .01705791   .00001258
 lower 1.8190127  -1.1237093  -6.3622962  23.527891
 upper 7.8919987  -.5492302  -.64414044  58.202102
    df   70     70     70     70
    crit 1.9944371  1.9944371  1.9944371  1.9944371
      eform 0       0       0       0
```

```
. matrix rtable = r(table)
```
The displayed results returned by `regress` are saved in `r(table)`. We create the matrix `r_table` as the transpose of `r(table)` because we want to see the variable names in rows.

### Example 5: Export selected estimation results

Suppose we want to export only the point estimates and confidence intervals. The point estimates and confidence intervals in the regression table can be extracted from the matrix `r_table`. We can extract columns 1, 5, and 6 from `r_table`, combine them, and assign them to another new matrix, `r_table`.

```
. matrix r_table = rtable[1...,1], rtable[1...,5..6]
```

Then, we export `r_table` to the document as a table with the name `tbl2`.

```
. putdocx table tbl2 = matrix(r_table), nformat(%9.3f) rownames colnames
> border(start, nil) border(insideH, nil) border(insideV, nil) border(end, nil)
```

In this table, all values imported from the matrix have been formatted as `%9.3f`. In addition, the row and column names of the matrix `r_table` are included as the first row and first column of the table. We keep only the top and bottom borders of the table by specifying `nil` for the leading edge border (`start`), trailing edge border (`end`), inside horizontal edges border (`insideH`), and inside vertical edges border (`insideV`).

The column names from the matrix may not be exactly what we want; we can modify them by customizing the corresponding cells. We can reset the contents and the horizontal alignment of the cells on the first row to give the columns new titles.

```
. putdocx table tbl2(1,2) = ("Coef."), halign(right)
. putdocx table tbl2(1,3) = ("[95% Conf. Interval]"), halign(right) colspan(2)
```

Afterward, we add back the bottom border of the first row and right-align the cells on the rest of the rows by looping over each cell; see [P] `forvalues`.

```
. forvalues i = 1/5 {
  2.   forvalues j=1/4 {
  3.     if ‘i’==1 {
  4.       putdocx table tbl2(‘i’,‘j’), border(bottom)
  5.     }
  6.     else {
  7.       putdocx table tbl2(‘i’,‘j’), halign(right)
  8.     }
  9.   }
 10. }
```
Our final table appears in the document as follows:

![Table Image]

We can now type

```
.putdocx save example.docx
```

to save the document that we created as `example.docx`.

### Advanced uses

In this section, we begin a new document and add some more-advanced tables to it.

```
.putdocx begin
```

Afterward, we can append these tables to the first set of examples by using

```
.putdocx save example.docx, append
```

> **Example 6: Create table from components**

Sometimes, we might need a table with a complicated layout. It may be difficult for us to figure out the dimension of the table and the content of each cell. In this situation, we can consider building the table in pieces and combining them. For illustrative purposes, we use the table created in example 5. The table can be considered to comprise two parts, the header and the bottom. We first create a table for each part.

The header part is specified as a $1 \times 2$ table with borders removed and contents aligned to the right.

```
.putdocx table tbl31 = (1,2), memtable border(all, nil)
.putdocx table tbl31(1,1) = ("Coef."), halign(right)
.putdocx table tbl31(1,2) = ("[95% Conf. Interval]"), halign(right)
```

The bottom part is created as another table by using the same Stata matrix from example 5, `r_table`. Again, we remove all borders and align all contents to the right.
Notice that both tables are created with the `memtable` option, which declares that they be created in memory rather than added to the document. This is required for our next steps.

At last, we create a $2 \times 1$ table named `tbl3`, in which the first cell contains `tbl31` and the second cell contains `tbl32`. In addition, we remove its leading edge border and trailing edge border.

```plaintext
> putdocx table tbl3 = (2,1), border(start, nil) border(end, nil)
> putdocx table tbl3(1,1) = table(tbl31)
> putdocx table tbl3(2,1) = table(tbl32)
```

This is a simple example of how to create a table using nested tables.

**Example 7: Create table dynamically**

In the previous example, we added a table in two steps. The first step was to create a table in the document. The second step was to fill in the contents for each cell. In this process, the dimensions of the table were often predetermined. Another way to add a table is to create it dynamically: start with a simple table and then add rows or columns to it gradually.

Returning to example 5, suppose we want to add an estimation table to the document containing the point estimates, their standard errors, the total number of observations, and the coefficient of determination. The estimation table looks like the following:

First, we create a $1 \times 2$ table with no borders and fill the single row with the dependent variable name, `mpg`. We also set the table width to be 4 inches and put the table in the center of the document.
Notice that each regressor in the model takes up 2 rows and 2 columns in the table, which means 4 cells. The cell in the first row and first column contains the variable name. The cell in the first row and second column contains the point estimate. The cell in the second row and second column contains the standard errors. Based on this logic, we add two rows for each regressor at the end of the table every time, and we fill in the content and format for each cell one by one.

```
.local row 1
.local vari 1
.foreach x in gear_ratio turn foreign _cons {
    2. putdocx table tbl4('row',.), addrows(2)
    3.
    4. local b: display %9.3f rtable['vari',1]
    5. local se: display %9.3f rtable['vari',2]
    6. local ++vari
    7.
    8. local ++row
    9. putdocx table tbl4('row',1) = ('x'), halign(right)
    10. putdocx table tbl4('row',2) = ('b'), halign(right)
    11. local ++row
    12. local se = strtrim('se')
    13. putdocx table tbl4('row',2) = ('se'), halign(right)
    14. }
```

Afterward, we add three more rows to the end of the table for the number of observations, the coefficient of determination, and a note as a footer.

```
.putdocx table tbl4('row',.), addrows(3)
```

We then add each statistic to the table.

```
.local ++row
.putdocx table tbl4('row',1) = (N), border(top) halign(right)
.putdocx table tbl4('row',2) = (e(N)), border(top) halign(right)
.local ++row
.local r2: display %9.3f e(r2)
.putdocx table tbl4('row',1) = (R2), halign(right)
.putdocx table tbl4('row',2) = (r2), halign(right)
```

Finally, we add the footnote “Note: standard errors in parentheses” that spans two columns with a border on the top to separate the note from the rest of the table.

```
.local ++row
.putdocx table tbl4('row',1) = (Note: standard errors in parentheses),
> colspan(2) border(top)
```

---

> Example 8: Nesting images in a table

We might want to add various images to the document and align them side by side, row by row, or both. To be more clear, we use an example to illustrate this purpose. In this example, we use another dataset—the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981).
456

putdocx — Generate Office Open XML (.docx) file

First, we fit a three-way full factorial model of systolic blood pressure on age group, sex, and
body mass index (BMI). Then, we estimate the predictive margins for each combination of agegrp
and sex at levels of BMI from 10 through 40 at intervals of 10 and graph the results.
. use http://www.stata-press.com/data/r15/nhanes2, clear
. regress bpsystol agegrp##sex##c.bmi
(output omitted )
. forvalues v=10(10)40 {
2.
margins agegrp, over(sex) at(bmi=‘v’)
3.
marginsplot
4.
graph export bmi‘v’.png
5. }
(output omitted )

Now, we want to add those four plots into the document, requiring that the margins plots for
bmi=10 and bmi=20 lay side by side on top of the other two side-by-side margins plots for bmi=30
and bmi=40. It is also required that each plot have a subtitle indicating the level of BMI and that the
final figure have a title. This complicated layout can be easily accomplished using putdocx table.
We start with a 2 × 2 table and remove all of its borders. In each cell, we add a plot and then
append center-aligned text to it. Finally, we add another row to the end of the table and fill it with
the title for the figure.
. putdocx table tbl5 = (2,2), border(all,nil)
. putdocx table tbl5(1,1)=image(bmi10.png)
. putdocx table tbl5(1,1)=("(a) bmi=10"), append halign(center)
.
.
.

[M-5] xl( ) — Excel file I/O class
**Description**

`putexcel` writes Stata expressions, matrices, images, and returned results to an Excel file. It may also be used to format cells in an Excel worksheet. This allows you to automate exporting and formatting of, for example, Stata estimation results. Excel 1997/2003 (.xls) files and Excel 2007/2010 and newer (.xlsx) files are supported.

`putexcel set` sets the Excel file to create, modify, or replace in subsequent `putexcel` commands. You must set the destination file before using any other `putexcel` commands. `putexcel clear` clears the file information set by `putexcel set`. `putexcel describe` displays the file information set by `putexcel set`.

For the advanced syntax that lets you simultaneously write multiple output types, see [P] `putexcel advanced`.

**Quick start**

Declare the first sheet of `myresults.xlsx` to be the destination workbook for subsequent `putexcel` commands

```stata
putexcel set myresults
```

As above, but use a new sheet named Estimation Results and replace the existing workbook

```stata
putexcel set myresults, replace sheet("Estimation Results")
```

Write the text “Coefficients” to cell B1

```stata
putexcel B1 = "Coefficients"
```

Add variable names and estimated coefficients in the column under “Coefficients” after `regress`, and format coefficients with two decimal places

```stata
matrix b = e(b)'
putexcel A2 = matrix(b), rownames nformat(number_d2)
```

Format the header row of the table with a bottom border and bold text

```stata
putexcel (A1:B1), bold border(bottom)
```

Add PNG of a `margins` plot saved to disk as `mymargins.png` where the upper-left corner is aligned with the upper-left corner of cell D2

```stata
marginsplot, name(mymargins)
graph export mymargins.png, name(mymargins)
putexcel D2 = picture(mymargins.png)
```

**Menu**

File > Export > Results to Excel spreadsheet (*.xls;*.xlsx)
Syntax

Set workbook for export

```
putexcel set filename [, set_options]
```

Write expression to Excel

```
putexcel ul_cell = exp [, export_options format_options]
```

Export Stata matrix to Excel

```
putexcel ul_cell = matrix(name) [, export_options format_options]
```

Export Stata graph, path diagram, or other picture to Excel

```
putexcel ul_cell = picture(filename)
```

Export returned results to Excel

```
putexcel ul_cell = returnset [, export_options]
```

Write formula to Excel

```
putexcel ul_cell = formula(formula) [, export_options]
```

Format cells

```
putexcel cellrange, format_options
```

Describe current export settings

```
putexcel describe
```

Clear current export settings

```
putexcel clear
```

ul_cell is a valid Excel upper-left cell specified using standard Excel notation, for example, A1 or D4.

cellrange is ul_cell or ul_cell:lr_cell, where lr_cell is a valid Excel lower-right cell, for example, A1, A1:D1, A1:A4, or A1:D4.

Output types

`exp` writes a valid Stata expression to a cell. See [U] 13 Functions and expressions. Stata dates and datetimes differ from Excel dates and datetimes. To properly export date and datetime values, use `asdate` and `asdatetime`.

`matrix(name)` writes the values from a Stata matrix to Excel. Stata determines where to place the data in Excel by default from the size of the matrix (the number of rows and columns) and the location you specified in `ul_cell`. By default, `ul_cell` contains the first element of `name`, and matrix row names and column names are not written.

`picture(filename)` writes a portable network graphics (.png), JPEG (.jpg), Windows metafile (.wmf), device-independent bitmap (.dib), enhanced metafile (.emf), or bitmap (.bmp) file to an Excel worksheet. The upper-left corner of the image is aligned with the upper-left corner of the specified `ul_cell`. The image is not resized. If `filename` contains spaces, it must be enclosed in double quotes.

`returnset` is a shortcut name that is used to identify a group of `return` values. It is intended primarily for use by programmers and by those who intend to do further processing of their exported results in Excel. `returnset` may be any one of the following:
formula(formula) writes an Excel formula to the cell specified in ul_cell. formula may be any valid Excel formula. Stata does not validate formulas; the text is passed literally to Excel.

Options

 sheet(sheetname [, replace ]) saves to the worksheet named sheetname. If there is no worksheet named sheetname in the workbook, then a new sheet named sheetname is created. If this option is not specified, the first worksheet of the workbook is used.

 replace permits putexcel set to overwrite sheetname if it exists in the specified filename.

 modify permits putexcel set to modify an Excel file.

 replace permits putexcel set to overwrite an existing Excel workbook. The workbook is overwritten when the first putexcel command is issued.

 overwritefmt causes putexcel to remove any existing cell formatting in the cell or cells to which it is writing new output. By default, all existing cell formatting is preserved.

 asdate tells putexcel that the specified exp is a Stata %td-formatted date that should be converted to an Excel date with mid/yyyy Excel date format.

 This option has no effect if an exp is not specified as the output type.

 asdatet ime tells putexcel that the specified exp is a Stata %tc-formatted datet ime that should be converted to an Excel datet ime with mid/yyyy h:mm Excel datet ime format.

 This option has no effect if an exp is not specified as the output type.

 asdatenum tells putexcel that the specified exp is a Stata %td-formatted date that should be converted to an Excel date number, preserving the cell’s format.

 This option has no effect if an exp is not specified as the output type.

 asdatetimenum tells putexcel that the specified exp is a Stata %tc-formatted datet ime that should be converted to an Excel datet ime number, preserving the cell’s format.

 This option has no effect if an exp is not specified as the output type.

 names specifies that matrix row names and column names be written into the Excel worksheet along with the matrix values. If you specify names, then ul_cell will be blank, the cell to the right of it will contain the name of the first column, and the cell below it will contain the name of the first row. names may not be specified with rownames or colnames.

 This option has no effect if matrix() is not specified as the output type.
rownames specifies that matrix row names be written into the Excel worksheet along with the matrix values. If you specify rownames, then ul_cell will contain the name of the first row. rownames may not be specified with names or colnames.

This option has no effect if matrix() is not specified as the output type.

colnames specifies that matrix column names be written into the Excel worksheet along with the matrix values. If you specify colnames, then ul_cell will contain the name of the first column. colnames may not be specified with names or rownames.

This option has no effect if matrix() is not specified as the output type.

colwise specifies that if a returnset is used, the values written to the Excel worksheet be written in consecutive columns. By default, the values are written in consecutive rows.

This option has no effect if a returnset is not specified as the output type.

nformat(excelnfmt) changes the numeric format of a cell range. Codes for commonly used formats are shown in the table of numeric formats in the Appendix. However, any valid Excel format is permitted. For information about creating your own formats, see the description of nformat() in Options of [P] putexcel advanced.

left sets the specified cells to have contents left-aligned within the cell. left may not be combined with right or hcenter. Right-alignment is the Excel default for numeric values and need not be specified when outputting numbers.

hcenter sets the specified cells to have contents horizontally centered within the cell. hcenter may not be combined with left or right.

right sets the specified cells to have contents right-aligned within the cell. right may not be combined with left or hcenter. Left-alignment is the Excel default for text and need not be specified when outputting strings.

top sets the specified cells to have contents vertically aligned with the top of the cell. top may not be combined with bottom or vcenter.

vcenter sets the specified cells to have contents vertically aligned with the center of the cell. vcenter may not be combined with top or bottom.

bottom sets the specified cells to have contents vertically aligned with the bottom of the cell. bottom may not be combined with top or vcenter.

txtindent(#) sets the text indention in each cell in a cell range. # must be an integer between 0 and 15.

txtrotate(#) sets the text rotation in each cell in a cell range. # must be an integer between 0 and 180 or equal to 255. txtrotate(0) is equal to no rotation and is the default. txtrotate(255) specifies vertical text. Values 1–90 rotate the text counterclockwise 1 to 90 degrees. Values 91–180 rotate the text clockwise 1 to 90 degrees.

txtwrap and notxtwrap specify whether or not the text is to be wrapped in a cell or within each cell in a range of cells. The default is no wrapping. notxtwrap has an effect only if the cell or cells were previously formatted to wrap. txtwrap may not be specified with shrinkfit.

shrinkfit and noshrinkfit specify whether or not the text is to be shrunk to fit in the cell width of a cell or in each cell of a range of cells. The default is no shrinking. noshrinkfit has an
putexcel — Export results to an Excel file

Effect only if the cell or cells were previously formatted to shrink text to fit. shrinkfit may not be specified with txtwrap.

merge tells Excel that cells in the specified cell range should be merged. merge may be combined with left, right, hcenter, top, bottom, and vcenter to format the merged cell. Merging cells that contain data in each cell will result in the upper-leftmost data being kept.

Once you have merged cells, you can refer to the merged cell by using any single cell from the specified cellrange. For example, if you specified a cellrange of A1:B2, you could refer to the merged cell using A1, B1, A2, or B2.

unmerge tells Excel to unmerge previously merged cells. When using unmerge, you only need to use a single cell from the merged cell in the previously specified cellrange.

---

Font

font(fontname [, size [, color]]) sets the font, font size, and font color for each cell in a cell range. If font() is not specified, the Excel defaults are preserved.

fontname may be any valid Excel font. If fontname includes spaces, then it must be enclosed in double quotes. What constitutes a valid Excel font is determined by the version of Excel that is installed on the user’s computer.

size is a numeric value that represents any valid Excel font size. The default is 12.

color may be one of the colors listed in the table of colors in the Appendix or may be a valid RGB value in the form "### ### ###". If no color is specified, then Excel workbook defaults are used.

italic and noitalic specify whether to italicize or unitalicize the text in a cell or range of cells. The default is for text to be unitalicized. noitalic has an effect only if the cell or cells were previously italicized.

bold and nobold specify whether to bold or unbold the text in a cell or range of cells. The default is for text to be unbold. nobold has an effect only if the cell or cells were previously formatted as bold.

underline and noununderline specify whether to underline the text or remove the underline from the text in a cell or range of cells. The default is for text not to be underlined. noununderline has an effect only if the cell or cells previously contained underlined text.

strikeout and nostrikeout specify whether to strikeout the text or remove the strikeout from the text in a cell or range of cells. The default is for text not to have a strikeout mark. nostrikeout has an effect only if the cell or cells previously had a strikeout mark.

script(sub|super|none) changes the script style of the cell. script(sub) makes all text in a cell or range of cells a subscript. script(super) makes all text in a cell or range of cells a superscript. script(none) removes all subscript or superscript formatting from a cell or range of cells. Specifying script(none) has an effect only if the cell or cells were previously formatted as subscript or superscript.

Border

border(border [, , style [, , color]]) sets the cell border, style, and color for a cell or range of cells.

border may be all, left, right, top, or bottom.

style is a keyword specifying the look of the border. The most common styles are thin, medium, thick, and double. The default is thin. For a complete list of border styles, see the Appendix. To remove an existing border, specify none as the style.
color may be one of the colors listed in the table of colors in the Appendix or may be a valid RGB value in the form "### ### ###". If no color is specified, then Excel workbook defaults are used.

dborder(direction [ , style [ , color ]]) sets the cell diagonal border direction, style, and color for a cell or range of cells.

direction may be down, up, or both. down draws a line from the upper-left corner of the cell to the lower-right corner of the cell or, for a range of cells, from the upper-left corner of ul_{cell} to the lower-right corner of lr_{cell}. up draws a line from the lower-left corner of the cell to the upper-right corner of the cell or, for a range of cells, from the lower-left corner of the area defined by ul_{cell}:lr_{cell} to the upper-right corner.

style is a keyword specifying the look of the border. The most common styles are thin, medium, thick, and double. The default is thin. For a complete list of border styles, see the Appendix. To remove an existing border, specify none as the style.

color may be one of the colors listed in the table of colors in the Appendix or may be a valid RGB value in the form "### ### ###". If no color is specified, then Excel workbook defaults are used.

fill

fpattern(pattern [ , fgcolor [ ,bgcolor ]]) sets the fill pattern, foreground color, and background color for a cell or range of cells.

pattern is a keyword specifying the fill pattern. The most common fill patterns are solid for a solid color (determined by fgcolor), gray25 for 25% gray scale, gray50 for 50% gray scale, and gray75 for 75% gray scale. A complete list of fill patterns is shown in the Appendix. To remove an existing fill pattern from the cell or cells, specify none as the pattern.

fgcolor specifies the foreground color. The default foreground color is black. fgcolor may be any of the colors listed in the table of colors in the Appendix or may be a valid RGB value in the form "### ### ###".

bgcolor specifies the background color. bgcolor may be any of the colors listed in the table of colors in the Appendix or may be a valid RGB value in the form "### ### ###". If no bgcolor is specified, then Excel workbook defaults are used.
Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Writing expressions and formatting cells
- Exporting summary statistics to Excel
- Export estimation results
- Export graphs and other images

Introduction

The putexcel command is a means of directly controlling the layout of an Excel file. As such, putexcel is designed to mimic the options and functionality of Excel, and many options of putexcel are simply pass-through arguments to Excel itself. In what follows, we provide documentation of how to use the putexcel command. However, for many options, such as the specification of valid numeric formats, font names, and font sizes, users are encouraged to also consult the help for their specific version of Excel.

putexcel may be used with Excel 1997/2003 (.xls) and Excel 2007/2010 and newer (.xlsx). putexcel looks at the file extension .xls or .xlsx to determine which Excel format to write. It is supported on Windows, Mac, and Linux.

putexcel also has an advanced syntax that allows you to write multiple types of output to different cells or cell ranges at a time; see [P] putexcel advanced.

Example 1: Setting the workbook and sheet

Before we can write to an Excel workbook using putexcel, we need to tell Stata what the destination is. We do this using the putexcel set command. For the next several examples, we will use an Excel file named myresults.xlsx and a sheet named Descriptive.

```
. putexcel set myresults.xlsx, sheet(Descriptive)
```

If we had not specified the sheet name, putexcel set would have defaulted to using the first sheet in the workbook.

Writing expressions and formatting cells

Although there are many uses for putexcel, one of the primary reasons to use the command is to keep track of the results of analyses in a single location for later use. The next several examples show how to export results to a single location for easy sharing and to create formatted tables that can be placed in a paper or poster.

Suppose we are analyzing data about the number of times young adults visited a news website. These data are contained in website.dta and described in detail in example 1 of [R] ivpoisson.
. use http://www.stata-press.com/data/r15/website
(Visits to website)
. describe
Contains data from http://www.stata-press.com/data/r15/website.dta
obs: 500 Visits to website
vars: 6 11 Feb 2016 14:45
size: 13,500

</tbody>
</table>

Sorted by:

We want to create a formatted table of summary statistics for men and women.

Example 2: Write expression to cell

We start by writing column headers to the first row of our worksheet.

. putexcel A1 = "Variable"
   file myresults.xlsx saved
. putexcel B1 = "Men"
   file myresults.xlsx saved
. putexcel C1 = "Women"
   file myresults.xlsx saved

Each of these commands opens the Excel workbook, writes the text to the specified cell, and then closes the workbook. We also use expressions to write out specific results (see example 4).

Example 3: Format a range of cells

We may also want to make the column headings bold and add a border underneath. We can format a range of cells by specifying a cell range and the appropriate formatting options.

. putexcel A1:C1, bold border(bottom)
   file myresults.xlsx saved

We also could have specified the bold and border() options each time we exported the column heading in example 2.

. putexcel A1 = "Variable", bold border(bottom)
   file myresults.xlsx saved
. putexcel B1 = "Men", bold border(bottom)
   file myresults.xlsx saved
. putexcel C1 = "Women", bold border(bottom)
   file myresults.xlsx saved

Whether you apply formatting at the time you write to Excel or for a range will likely depend on the number of options you have and the number of cells affected by common formatting options.
Exporting summary statistics to Excel

We can use `putexcel` to write summary statistics to an Excel worksheet. The available summary statistics are determined by `return results`. The returned results are documented in the `Stored results` section of the command’s manual entry or help. You can also see what is returned by typing `return list` or `ereturn list`.

➢ Example 4: Export selected statistics

To export a specific statistic, we use the expression output type. For example, we might want a table that has the number of observations for men and women followed by means for each variable, which we show in example 5.

We can obtain counts many ways in Stata. Here we use the `summarize` command and restrict the command to males (`female==0`). We use `visits`, but any continuous variable without missing values would have worked just as well. `r(N)` stores the number of observations.

```stata
. summarize visits if female==0
Variable | Obs Mean Std. Dev. Min Max
---|---|---|---|---|---
visits | 257 5.105058 3.893185 1 27
. putexcel B2 = `r(N)'
file myresults.xlsx saved
```

A more direct way to obtain the number of observations is with the `count` command.

```stata
. count if female==1
   243
. putexcel C2 = `r(N)'
file myresults.xlsx saved
```

Notice that we typed `r(N)` instead of "r(N)". The `'` tell Stata to fill in the numeric value associated with `r(N)` instead of exporting the text, known as macro substitution; see [P] macro. If we wanted to treat the contents of `r(N)`, or any other return value, like a string, we could have typed "'r(N)'".

➢ Example 5: Export frequency tables

You can use `putexcel` in Stata to create tables in Excel by using the `matrix()` output type. Suppose we want create a table of means for each variable for each value of `female`. We can use `tabstat` with the `save` option and then check the return values with `return list` to determine what values to output.

```stata
. tabstat visits ad time phone frfam, by(female) save
Summary statistics: mean
    by categories of: female (Female)
female | visits       ad           time       phone       frfam
        | 5.105058 2.175097 3.222412 3.164086 3.654280
  0    | 5.105058 2.175097 3.222412 3.164086 3.654280
  1    | 4.946502 2.098765 3.161276 3.155391 3.676708
Total | 5.028       2.138       3.1927       3.15986    3.66518
```

```stata
. tabstat visits ad time phone frfam, by(female) save
Summary statistics: mean
    by categories of: female (Female)
female | visits       ad           time       phone       frfam
        | 5.105058 2.175097 3.222412 3.164086 3.654280
  0    | 5.105058 2.175097 3.222412 3.164086 3.654280
  1    | 4.946502 2.098765 3.161276 3.155391 3.676708
Total | 5.028       2.138       3.1927       3.15986    3.66518
```
First, we transpose the row vectors \( \mathbf{r(Stat1)} \) and \( \mathbf{r(Stat2)} \), which contain the means, so that the values are written in a column under each heading. We want the variable names to be included, so for males, which is the first matrix we output, we include the \texttt{rownames} option. Because we want the values in B3 and the row names of the matrix in A3, we specify A3. We use \texttt{nformat(number\_d2)} to format the means with two decimal places. For females, we do not need to specify the names again, so we just specify the cell where we want the data to be written.

\begin{verbatim}
. matrix male = r(Stat1)'
. matrix female = r(Stat2)'
. putexcel A3 = matrix(male), rownames nformat(number\_d2)
    file myresults.xlsx saved
. putexcel C3 = matrix(female), nformat(number\_d2)
    file myresults.xlsx saved
\end{verbatim}

The above commands give a final table of frequencies and means that looks like this:

![Excel table](image)

**Export estimation results**

A similar approach to that used in example 5 can be used to export estimation results. Suppose we want to fit a linear regression model of \texttt{visits} as a function of \texttt{ad}, \texttt{female}, and \texttt{time} using \texttt{regress} and we want to export formatted results.
Example 6: Export point estimates and sample size

We start by using `putexcel set` again to create a new worksheet for our regression results.

```
    . putexcel set myresults.xlsx, sheet(Estimation)
```

We want to give our coefficients the title “Coef.” in the table we create, so we use an expression to write this to cell B1. We create a new matrix for our coefficients as the transpose of the values of `e(b)`. We use column A row 2 as the starting location for the matrix row labels, and we use column B row 2 as the starting location for the coefficients; to do this, we only need to specify the upper-left cell (A2) and the `rownames` option. To make our table more readable, we format the coefficient estimates with two decimal places by using `nformat()` and add a bottom border under the estimates.

```
    . putexcel B1 = "Coef."
    . putexcel A2 = matrix(b)', rownames nformat(number_d2)
    . putexcel A5:B5, border(bottom)
```

We then add a right-aligned and italicized “N=” in column A row 6 and the sample size from `e(N)` in column B row 6. We use a medium border under this row instead of the default thin border to indicate that the table is complete.

```
    . putexcel A6 = "N=", italic right border(bottom, medium)
    . putexcel B6 = matrix(e(N)), nformat(number_sep) border(bottom, medium)
```

We regress visits ad female time

```
    . regress visits ad female time
```

```

The above commands create a table that looks like this:

![Excel table example](image)

If you are going to export more complex tables or many objects, you should use the advanced syntax of `putexcel`; see [P] `putexcel advanced`.

### Export graphs and other images

You can export PNG, JPEG, and other image formats to Excel with `putexcel`. To export a Stata graph, you must first use `graph export` to convert the Stata graph to one of the supported image formats.

#### Example 7: Export Stata graph

We may want to add a histogram about the number of advertisements viewed to our set of descriptive results. We can use the `histogram` command and then `graph export` to create a PNG file of our histogram.
Next, we use `putexcel set` to switch back to the Excel sheet named *Descriptive*, and then we output the graph to Excel with the `picture()` output type.

```
  . putexcel set myresults.xlsx, sheet(Descriptive)
  . putexcel E2 = picture(ads.png)
  file myresults.xlsx saved
```

This adds the graph with the upper-left corner of the graph aligned in the upper-left corner of cell E2. Graphs are not resized by `putexcel`, but you can change the size with the `graph export` command; see [G-2] `graph export`.

⚠️ Technical note

See the technical notes *Excel data size limits* and *Dates and times* in [D] `import excel`.

[M-5] xl() — Excel file I/O class
Description

`putexcel` with the advanced syntax may be used to simultaneously write Stata expressions, matrices, images, and stored results to an Excel file. It may also be used to format existing contents of cells in a worksheet. This syntax is intended for use by programmers of commands that call `putexcel` in the background and by other advanced users. Excel 1997/2003 (.xls) files and Excel 2007/2010 and newer (.xlsx) files are supported. A simplified version of the syntax is documented in [P] `putexcel`.

`putexcel set` sets the Excel file to create, modify, or replace in subsequent `putexcel` commands. You must set the destination file before using any other `putexcel` commands. `putexcel clear` clears the file information set by `putexcel set`. `putexcel describe` displays the file information set by `putexcel set`.

Quick start

Declare the first sheet of `myresults.xlsx` to be the destination workbook for subsequent `putexcel` commands

```stata
putexcel set myresults
```

As above, but use a sheet named Estimation Results and replace that sheet if it exists

```stata
putexcel set myresults, sheet("Estimation Results", replace)
```

Write estimation results in `e(b)` to column B, starting in row 2, with the results formatted to have two decimal places, matrix row names in column A, and the title “Coefs.” in cell B1

```stata
matrix b=e(b)'
putexcel B1="Coefs." A2=matrix(b), rownames nformat(number_d2)
```

Add a thin border under cells A1 to B1 and italicize the text

```stata
putexcel (A1:B1), border(bottom) italic
```

Write “Some text that is too long to fit” to cell D1 and set the text to wrap within the cell

```stata
putexcel D1="Some text that is too long to fit", txtwrap
```

Merge D1 with D2, E1, and E2, and horizontally and vertically center

```stata
putexcel (D1:E2), merge hcenter vcenter
```

Menu

File > Export > Results to Excel spreadsheet (*.xls;*.xlsx)
Syntax

Set workbook for export

```plaintext
putexcel set filename [, set_options]
```

Specify formatting and output

```plaintext
putexcel spec1 [ spec2 [ ... ]] [, export_options format_options]
```

Describe current export settings

```plaintext
putexcel describe
```

Clear current export settings

```plaintext
putexcel clear
```

`spec` may be `ul_cell` or `cellrange` of the form `ul_cell:lr_cell` if no output is to be written or may be one of the following output types:

- `ul_cell = exp`
- `ul_cell:lr_cell = exp`
- `ul_cell = matrix(name)`
- `ul_cell = picture(filename)`
- `ul_cell = formula(formula)`
- `ul_cell = returnset`

`ul_cell` is a valid Excel upper-left cell specified using standard Excel notation, and `lr_cell` is a valid Excel lower-right cell. If you specify `ul_cell` as the output location multiple times, the rightmost specification is the one written to the Excel file.

| **colnames**  
also write matrix column names for matrix `name`; may not be combined with `names` or `rownames` |
| **colwise**  
write results in `returns`et to consecutive columns instead of rows |
### Output types

*exp* writes a valid Stata expression to a cell. See [U] 13 Functions and expressions. Stata dates and datetimes differ from Excel dates and datetimes. To properly export date and datetime values, use `asdate` and `asdatetime`.

*matrix(*name*)*) writes the values from a Stata matrix to Excel. Stata determines where to place the data in Excel by default from the size of the matrix (the number of rows and columns) and the location you specified in *ul_cell*. By default, *ul_cell* contains the first element of *name*, and matrix row names and column names are not written.

*picture(*filename*)*) writes a portable network graphics (.png), JPEG (.jpg), Windows metafile (.wmf), device-independent bitmap (.dib), enhanced metafile (.emf), or bitmap (.bmp) file to an Excel worksheet. The upper-left corner of the image is aligned with the upper-left corner of the specified *ul_cell*. The image is not resized. If *filename* contains spaces, it must be enclosed in double quotes.

Returnset is a shortcut name that is used to identify a group of return values. *returnset* may be any one of the following:

<table>
<thead>
<tr>
<th>Returnset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>returnset</td>
<td><em>return</em> values</td>
</tr>
</tbody>
</table>
**returnset**

<table>

</tr>
<tr>
<td>rmatrices</td>
<td>rmatrixnames</td>
</tr>
<tr>
<td>e*</td>
<td>enames</td>
</tr>
<tr>
<td>r*</td>
<td>rnames</td>
</tr>
</tbody>
</table>

`formula(formula)` writes an Excel formula to the cell specified in `ul_cell`. `formula` may be any valid Excel formula. Stata does not validate formulas; the text is passed literally to Excel.

**Options**

- `set` saves to the worksheet named `sheetname`. If there is no worksheet named `sheetname` in the workbook, then a new sheet named `sheetname` is created. If this option is not specified, the first worksheet of the workbook is used.

  - `replace` permits `putexcel set` to overwrite `sheetname` if it exists in the specified `filename`.

- `modify` permits `putexcel set` to modify an Excel file.

- `replace` permits `putexcel set` to overwrite an existing Excel workbook. The workbook is overwritten when the first `putexcel` command is issued.

- `overwritefmt` causes `putexcel` to remove any existing cell formatting in the cell or cells to which it is writing new output. By default, all existing cell formatting is preserved.

- `asdate` tells `putexcel` that the specified `exp` is a Stata `%td`-formatted date that should be converted to an Excel date with `m/d/yyyy` Excel date format.

  This option has no effect if an `exp` is not specified as one of the output types.

- `asdatetime` tells `putexcel` that the specified `exp` is a Stata `%tc`-formatted datetime that should be converted to an Excel datetime with `m/d/yyyy h:mm` Excel datetime format.

  This option has no effect if an `exp` is not specified as one of the output types.

- `asdatenum` tells `putexcel` that the specified `exp` is a Stata `%td`-formatted date that should be converted to an Excel date number, preserving the cell’s format.

  This option has no effect if an `exp` is not specified as one of the output types.

- `asdatetime` tells `putexcel` that the specified `exp` is a Stata `%tc`-formatted datetime that should be converted to an Excel datetime number, preserving the cell’s format.

  This option has no effect if an `exp` is not specified as one of the output types.

- `names` specifies that matrix row names and column names be written into the Excel worksheet along with the matrix values. If you specify `names`, then `ul_cell` will be blank, the cell to the right of it will contain the name of the first column, and the cell below it will contain the name of the first row. `names` may not be specified with `rownames` or `colnames`.

  This option has no effect if `matrix()` is not specified as one of the output types.
rownames specifies that matrix row names be written into the Excel worksheet along with the matrix values. If you specify rownames, then ul_cell will contain the name of the first row. rownames may not be specified with names or colnames.

This option has no effect if matrix() is not specified as one of the output types.

colnames specifies that matrix column names be written into the Excel worksheet along with the matrix values. If you specify colnames, then ul_cell will contain the name of the first column. colnames may not be specified with names or rownames.

This option has no effect if matrix() is not specified as one of the output types.

colwise specifies that if a returnset is used, the values written to the Excel worksheet be written in consecutive columns. By default, the values are written in consecutive rows.

This option has no effect if a returnset is not specified as one of the output types.

nformat(excelnfmt) changes the numeric format of a cell range. Any valid Excel format is permitted. Formats are formed from combinations of the following symbols.

<table>
<thead>
<tr>
<th>Symbol</th>

</tbody>
</table>

Formats that contain spaces must be enclosed in double quotes. A list of codes for common numeric formats is also shown in the Appendix of [P] putexcel.

left sets the specified cells to have contents left-aligned within the cell. left may not be combined with right or hcenter. Right-alignment is the Excel default for numeric values and need not be specified when outputting numbers.

hcenter sets the specified cells to have contents horizontally centered within the cell. hcenter may not be combined with left or right.

right sets the specified cells to have contents right-aligned within the cell. right may not be combined with left or hcenter. Left-alignment is the Excel default for text and need not be specified when outputting strings.
top sets the specified cells to have contents vertically aligned with the top of the cell. top may not be combined with bottom or vcenter.

vcenter sets the specified cells to have contents vertically aligned with the center of the cell. vcenter may not be combined with top or bottom.

bottom sets the specified cells to have contents vertically aligned with the bottom of the cell. bottom may not be combined with top or vcenter.

txtindent(#) sets the text indention in each cell in a cell range. # must be an integer between 0 and 15.

txtrotate(#) sets the text rotation in each cell in a cell range. # must be an integer between 0 and 180 or equal to 255. txtrotate(0) is equal to no rotation and is the default. txtrotate(255) specifies vertical text. Values 1–90 rotate the text counterclockwise 1 to 90 degrees. Values 91–180 rotate the text clockwise 1 to 90 degrees.

txtwrap and notxtwrap specify whether or not the text is to be wrapped in a cell or within each cell in a range of cells. The default is no wrapping. notxtwrap has an effect only if the cell or cells were previously formatted to wrap. txtwrap may not be specified with shrinkfit.

shrinkfit and noshrinkfit specify whether or not the text is to be shrunk to fit in the cell width of a cell or in each cell of a range of cells. The default is no shrinking. noshrinkfit has an effect only if the cell or cells were previously formatted to shrink text to fit. shrinkfit may not be specified with txtwrap.

merge tells Excel that cells in the specified cell range should be merged. merge may be combined with left, right, hcenter, top, bottom, and vcenter to format the merged cell. Merging cells that contain data in each cell will result in the upper-leftmost data being kept.

Once you have merged cells, you can refer to the merged cell by using any single cell from the specified cellrange. For example, if you specified a cellrange of A1:B2, you could refer to the merged cell using A1, B1, A2, or B2.

unmerge tells Excel to unmerge previously merged cells. When using unmerge, you only need to use a single cell from the merged cell in the previously specified cellrange.

Font

font(fontname [, size [, color ]]) sets the font, font size, and font color for each cell in a cell range. If font() is not specified, the Excel defaults are preserved.

fontname may be any valid Excel font. If fontname includes spaces, then it must be enclosed in double quotes. What constitutes a valid Excel font is determined by the version of Excel that is installed on the user’s computer.

size is a numeric value that represents any valid Excel font size. The default is 12.

color may be a valid RGB value in the form "### ### ###" or may be one of the colors listed in the table of colors in the Appendix in [P] putexcel. If no color is specified, then Excel workbook defaults are used.

italic and noitalic specify whether to italicize or unitalicize the text in a cell or range of cells. The default is for text to be unitalicized. noitalic has an effect only if the cell or cells were previously italicized.

bold and nobold specify whether to bold or unbold the text in a cell or range of cells. The default is for text to be unbolded. nobold has an effect only if the cell or cells were previously formatted as bold.
underline and nounderline specify whether to underline the text or remove the underline from the text in a cell or range of cells. The default is for text not to be underlined. nounderline has an effect only if the cell or cells previously contained underlined text.

strikeout and nostrikeout specify whether to strikeout the text or remove the strikeout from the text in a cell or range of cells. The default is for text not to have a strikeout mark. nostrikeout has an effect only if the cell or cells previously had a strikeout mark.

script(sub | super | none) changes the script style of the cell. script(sub) makes all text in a cell or range of cells a subscript. script(super) makes all text in a cell or range of cells a superscript. script(none) removes all subscript or superscript formatting from a cell or range of cells. Specifying script(none) has an effect only if the cell or cells were previously formatted as subscript or superscript.

```
border( [border, style[, color]]) sets the cell border, style, and color for a cell or range of cells. border may be all, left, right, top, or bottom.

style is a keyword specifying the look of the border. The most common styles are thin, medium, thick, and double. The default is thin. For a complete list of border styles, see the Appendix in [P] putexcel. To remove an existing border, specify none as the style.

color may be a valid RGB value in the form "### ### ###" or may be one of the colors listed in the table of colors in the Appendix in [P] putexcel. If no color is specified, then Excel workbook defaults are used.
```

dborder( [direction, style[, color]]) sets the cell diagonal border direction, style, and color for a cell or range of cells.

direction may be down, up, or both. down draws a line from the upper-left corner of the cell to the lower-right corner of the cell or, for a range of cells, from the upper-left corner of ul_cell to the lower-right corner of lr_cell. up draws a line from the lower-left corner of the cell to the upper-right corner of the cell or, for a range of cells, from the lower-left corner of the area defined by ul_cell:lr_cell to the upper-right corner.

style is a keyword specifying the look of the border. The most common styles are thin, medium, thick, and double. The default is thin. For a complete list of border styles, see the Appendix in [P] putexcel. To remove an existing border, specify none as the style.

```
color may be a valid RGB value in the form "### ### ###" or may be one of the colors listed in the table of colors in the Appendix in [P] putexcel. If no color is specified, then Excel workbook defaults are used.
```

```
fpattern( [pattern, fgcolor[, bgcolor]]) sets the fill pattern, foreground color, and background color for a cell or range of cells.

pattern is a keyword specifying the fill pattern. The most common fill patterns are solid for a solid color (determined by fgcolor), gray25 for 25% gray scale, gray50 for 50% gray scale, and gray75 for 75% gray scale. A complete list of fill patterns is shown in the Appendix of [P] putexcel. To remove an existing fill pattern from the cell or cells, specify none as the pattern.

fgcolor specifies the foreground color. The default foreground color is black. fgcolor may be a valid RGB value in the form "### ### ###" or may be any of the colors listed in the table of colors in the Appendix in [P] putexcel.
```
bgcolor specifies the background color. bgcolor may be a valid RGB value in the form "### ###" or may be any of the colors listed in the table of colors in the Appendix in [P] putexcel. If no bgcolor is specified, then Excel workbook defaults are used.

Remarks and examples

If you have not already read Remarks and examples in [P] putexcel, please do so now. The examples here build on the examples shown there.

Remarks are presented under the following headings:

- Writing expressions and formatting cells
- Using formulas
- Exporting estimation results

Writing expressions and formatting cells

Before we can write to an Excel workbook using putexcel, we need to tell Stata what the destination is. We do this using the putexcel set command. For the next several examples, we will use an Excel file named myresults2.xlsx. We will begin with a sheet named Descriptive.

```
.putexcel set myresults2.xlsx, sheet(Descriptive)
```

If we had not specified the sheet name, putexcel would have defaulted to using the first sheet in the workbook.

Example 1: Write multiple expressions and format cells simultaneously

Suppose we want to write the same headers and format them as shown in example 2 and example 3 of [P] putexcel. Using the advanced syntax of putexcel, we can do this with a single putexcel command.

```
.putexcel A1="Variable" B1="Men" C1="Women", bold border(bottom)
.file myresults2.xlsx saved
```

Rather than beginning with the table headers, we could improve record keeping by including the date we generated the results. To do this, we can use the system parameter, or c-class return value, c(current_date), which will add a string date in the format dd Mon yyyy; see [P] creturn. We also merge cells A1 and B1 for aesthetic reasons. Notice that we type "'c(current_date)'" instead of "c(current_date)". The ‘’ indicate macro substitution; see [P] macro. We specify replace as a suboption to sheet() in a new putexcel set command to overwrite our previous output.

```
.putexcel set myresults2.xlsx, sheet(Descriptive, replace)
.putexcel A1 = "Results last updated" D1 = "'c(current_date)'"
.file myresults2.xlsx saved

.putexcel (A1:C1), merge
.file myresults2.xlsx saved

.putexcel A2="Variable" B2="Men" C2="Women", bold border(bottom)
.file myresults2.xlsx saved
```
The above commands give an Excel file with a header row that looks like this:

![Excel spreadsheet screenshot]

### Using formulas

Writing Excel formulas is useful when you want to perform calculations using the output of Stata commands. Formulas are passed verbatim to Excel, so you must use the correct Excel function (not Stata function) for what you want to accomplish. You may find it helpful to experiment in Excel first and then copy the formula over to your do-file to keep a record of your work and in case you need to run your analysis again later.

#### Example 2: Adding a total row and total column

In example 4 of [P] putexcel, we obtained the number of females and number of males in the website dataset and wrote these out to Excel. Suppose instead that we want the number of males and females at each number of visits and the total number of visits.

We can change the heading for the first column from “Variable” to “Number of visits” and add a column for “Total”. We specify the txtwrap option with our putexcel command so that the long text “Number of visits” wraps within cell A2.

We use the matcell() option with tabulate to save the cell frequencies to a matrix and the matrow() option to save the row values from the table.
. use http://www.stata-press.com/data/r15/website
(Visits to website)
. putexcel A2="Number of visits" D2="Total", txtwrap bold border(bottom)
file myresults2.xlsx saved
. tabulate visits female, matrow(nvisits) matcell(freq)

<table>

<td>500</td>
</tr>
</tbody>
</table>

Totals, however, are not saved. By using formulas in Excel, we can add the row and column totals. Our results will begin on row 3, so we will want to begin calculating row totals here. For example, in Excel the row total for males (column B) and females (column C) in row 3 is D3=B3+C3. The fastest way to write this formula multiple times for each row is to use **forvalues;** see [P] **forvalues.**

. forvalues i=3/24 {
2.      putexcel D'='formula(B'+'C')
3. }
file myresults2.xlsx saved
(output omitted)

We also want column totals. For this, it is easier to use Excel’s **SUM()** function. We supply this as the **formula()** output type and add a border above the total row to set it apart from the rest of the table.

. putexcel A25="Total" B25=formula(SUM(B3:B24)) C25=formula(SUM(C3:C24))
> D25=formula(SUM(D3:D24)), bold border(top)
file myresults2.xlsx saved
Exporting estimation results

We start by using `putexcel` set again to create a new worksheet for our regression results.

```
. putexcel set myresults2.xlsx, sheet(Estimation)
```

Example 3: Export point estimates and formatted confidence intervals

We continue from example 6 of [P] `putexcel`, where we gave the coefficients the title “Coef.”. Here we add a column named “C.I.” for the confidence interval, which we center in cells C1 and D1.

```
. putexcel B1="Coef." C1="C.I."
file myresults2.xlsx saved
. putexcel (C1:D1), merge hcenter
file myresults2.xlsx saved
```

We fit the same model that we did in example 6 of [P] `putexcel`. We copy the r-class return `r(table)`, which contains the values that were returned by the command in the estimation results table, into a new matrix named `table`.

```
. quietly regress visits ad female time
. matrix table = r(table)
. matrix list table
```

<table>
<thead>
<tr>
<th></th>
<th>ad</th>
<th>female</th>
<th>time</th>
<th>_cons</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>.79961794</td>
<td>-.04679974</td>
<td>.82961995</td>
<td>.69243389</td>
</tr>
<tr>
<td>se</td>
<td>.05165911</td>
<td>.2096816</td>
<td>.04366007</td>
<td>.20079144</td>
</tr>
<tr>
<td>t</td>
<td>15.47874</td>
<td>-.22319432</td>
<td>19.001801</td>
<td>3.448523</td>
</tr>
<tr>
<td>pvalue</td>
<td>2.235e-44</td>
<td>.82347616</td>
<td>6.794e-61</td>
<td>.00061166</td>
</tr>
<tr>
<td>ll</td>
<td>-.69812028</td>
<td>-.45877341</td>
<td>.74383847</td>
<td>.29792725</td>
</tr>
<tr>
<td>ul</td>
<td>.90111561</td>
<td>.36517393</td>
<td>.91540143</td>
<td>1.0869405</td>
</tr>
<tr>
<td>df</td>
<td>496</td>
<td>496</td>
<td>496</td>
<td>496</td>
</tr>
<tr>
<td>crit</td>
<td>1.9647583</td>
<td>1.9647583</td>
<td>1.9647583</td>
<td>1.9647583</td>
</tr>
</tbody>
</table>

We then select row 1 for the coefficients (b), row 5 for the lower limit of the confidence interval (ll), and row 6 for the upper limit of the confidence interval (ul) into separate vectors. We take the transpose to ensure that our results for each variable are in a row rather than in a column when we write them out. We specify `nformat(number_d2)` for the coefficients, but we will specify a custom format for the confidence interval. We also add the `rownames` option so that the variable names are written out along with the coefficient estimates.

```
. matrix b = table[1, 1...]
. matrix ll = table[5, 1...]
. matrix ul = table[6, 1...]
. putexcel A2=matrix(b), rownames nformat(number_d2)
file myresults2.xlsx saved
```

We want our confidence interval to be displayed as (0.74 to 0.92), taking `time`, for example. That is, the numbers should have a 0 before the decimal and be rounded to two decimal places. The lower and upper limits should be separated by the word “to”, and the confidence interval should be enclosed in parentheses.

We specify our format in two steps. For the lower limit, we ensure that the negative sign will display inside the parentheses by specifying separate formats for positive and negative numbers. The code for positive numbers is specified before the semicolon. The code for negative numbers is specified after the semicolon. We add the word “to” so that it is printed between the lower and upper limit values. For the upper limit, the negative sign will display in front of the number by default, so we only have to specify one format.
Example 4: Export SEM estimates and path diagram

Continuing example 3, suppose we also fit a corresponding linear regression model using \texttt{sem} and want to export the coefficient estimates, confidence intervals, and the path diagram. We use the same general approach as in example 3 but with some modification. First, we specify the range of columns from table to be 1 through 4 when we create our \texttt{b}, \texttt{ll}, and \texttt{ul} vectors to exclude the variance.

```
. quietly sem (visits <- ad female time)
. matrix table = r(table)
. matrix list table
table[9,5]
  b     se     z     pvalue     ll     ul
df
visits: visits: visits: visits: var(e.vis\textasciitilde):
  ad  .79961794  -.04679974  .82961995  .69243389  5.4458576
  female  .05145206  .20884119  .04348508  .19998666  .34442628
  time  15.541029  -.22409249  19.078268  3.4624004
  _cons  .69243389  .05145206  .82961995  .04348508  5.4458576
  _cons  .30046724  .20884119  .74439077  .19998666  4.810958
  _cons  1.0844005  .90046212  3.148914  3.6252147  6.1645445
  _cons  .34442628  .36252147  .34442628  .36252147  6.1645445
  _cons  4.810958  1.959964  1.959964  1.959964  1.959964
  _cons  6.1645445  1.959964  1.959964  1.959964  1.959964
  _cons  1.959964  1.959964  1.959964  1.959964  1.959964
  _cons
  eform 0 0 0 0 0
```

If we wanted that term as well, we could select it separately. Because we do not need to specify row names again, we also specify the \texttt{ul\_cell} for \texttt{b} in reference to its values, not the labels this time. We use the same numeric format for \texttt{ll} and \texttt{ul}.

```
. matrix b = table[1, 1..4]'
. matrix ll = table[5, 1..4]'
. matrix ul = table[6, 1..4]'
```
Because we are adding estimation results, we change “Coef.” to “regress” and add a column heading for “sem”. As before, we include a merged column heading for the confidence interval. We center all column headings by using the `hcenter` option.

```
. putexcel B1="regress" E1="sem" F1="C.I.", hcenter
file myresults2.xlsx saved
. putexcel (F1:G1), merge
file myresults2.xlsx saved
```

Our table from example 3 now includes additional columns for our `sem` results:

![Excel Table with New Columns](image)

We might also want to export the path diagram for our model so that we can view it while looking at our results.

![Path Diagram](image)

The SEM Builder will allow you to save your path diagram as a PNG file, in addition to other file types; PNGs can be exported to Excel. We name our path diagram `visits_sem` and save it as a PNG, and we then output the file to Excel with the `picture()` output type.
. putexcel B6 = picture(visits_sem.png)
file myresults2.xlsx saved

This adds the path diagram with the upper-left corner aligned in the upper-left corner of cell B6.

Technical note

See the technical notes Excel data size limits and Dates and times in [D] import excel.

Description

putpdf writes paragraphs, images, and tables to a PDF file. It may also be used to format each object added. This allows you to automate exporting and formatting of, for example, Stata estimation results and also generate various reports based on those results.

Quick start

Create a document in memory on which subsequent contents are added

```stata
putpdf begin
```

Declare a paragraph to be added to the document and center the paragraph

```stata
putpdf paragraph, halign(center)
```

Append the text “This is paragraph text” to the paragraph declared above and format the text as bold

```stata
putpdf text ("This is paragraph text"), bold
```

Add a table named `tbl1` with three rows and four columns to the document

```stata
putpdf table tbl1 = (3,4)
```

Set the content of the cell on the first row and second column of the above table as “Cell 2” and align the text to the right

```stata
putpdf table tbl1(1,2) = ("Cell 2"), halign(right)
```

Add a table named `tbl2` with variable names and estimated coefficients after `regress`, and format coefficients with two decimal places

```stata
matrix b = e(b)'
putpdf table tbl2 = matrix(b), rownames nformat(%7.2f)
```

Add a PNG image saved as `myimg` to the document

```stata
putpdf paragraph
putpdf image myimg.png
```

Save the document in memory to disk as `myfile.pdf`

```stata
putpdf save myfile.pdf
```
Syntax

Create document for export

putpdf begin [, document_options]

Add paragraph to document

putpdf paragraph [, paragraph_options]

Add content to paragraph

putpdf text (exp) [, text_options]

Add image to paragraph

putpdf image filename [, image_options]

Add table to document

putpdf table tablename = (nrows, ncols) [, table_options]
putpdf table tablename = data(varlist) [if] [in] [, varnames obsno table_options]
putpdf table tablename = matrix(matname) [, nformat(,%fmt) rownames colnames table_options]
putpdf table tablename = mata(matname) [, nformat(,%fmt) table_options]
putpdf table tablename = returnset [, table_options]

Customize rows and columns

putpdf table tablename(i,.) [, row_col_options]
putpdf table tablename(.,j) [, row_col_options]

Add and format contents of table

putpdf table tablename(i,j) = (exp) [, cell_options]
putpdf table tablename(i,j) = image(filename) [, cell_options]
putpdf table tablename(i,j) = table(mem tablename) [, cell_options]
putpdf table tablename(i,j) [, cell_options

Add page break to document

putpdf pagebreak
Describe current document

```
putpdf describe
```

Describe table

```
putpdf describe tablename
```

Save document

```
putpdf save filename [, replace]
```

tablename specifies the name of a new table. The name must be a valid name according to Stata’s naming conventions; see [U] 11.3 Naming conventions.

nrows and ncols specify the number of rows and the number of columns in the new table.

matname specifies the name of an existing Stata matrix or Mata matrix.

returnset specifies a group of Stata return values and may be one of the following:

<table>
<thead>
<tr>
<th>returnset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>escalars</td>
<td>All ereturned scalars</td>
</tr>
<tr>
<td>rscalars</td>
<td>All returned scalars</td>
</tr>
<tr>
<td>emacros</td>
<td>All ereturned macros</td>
</tr>
<tr>
<td>rmacros</td>
<td>All returned macros</td>
</tr>
<tr>
<td>ematrices</td>
<td>All ereturned matrices</td>
</tr>
<tr>
<td>rmatrices</td>
<td>All returned matrices</td>
</tr>
<tr>
<td>e*</td>
<td>All ereturned scalars, macros, and matrices</td>
</tr>
<tr>
<td>r*</td>
<td>All returned scalars, macros, and matrices</td>
</tr>
</tbody>
</table>

mem_tablename specifies the name of a previously created table.

</table>

**fspec is**

*fspec* is

```
[fontname [, size [, color]]]
```

*fontname* may be any valid font installed on the user’s computer. If *fontname* includes spaces, then it must be enclosed in double quotes. The default font is *Helvetica*.

*size* is a numeric value that represents font size measured in points. The default is 11.

*color* sets the text color.

**bspec is**

```
[bordername [, bpattern [, bcolor]]]
```

*bordername* specifies the location of the border.

*bpattern* is a keyword specifying the look of the border. Possible patterns are *nil* and *single*. The default is *single*. To remove an existing border, specify *nil* as the *bpattern*.

*bcolor* specifies the border color.

*unit* may be in (inch), pt (point), cm (centimeter), or twip (twentieth of a point). An inch is equivalent to 72 points, 2.54 centimeters, or 1440 twips. The default is *in*.

*color* and *bcolor* may be one of the colors listed in the table of colors in the *Appendix*; a valid RGB value in the form ### ### ###, for example, 171 248 103; or a valid RRGGBB hex value in the form #######, for example, ABF867.
Output types

putpdf paragraph adds a new paragraph to the active document. The newly created paragraph becomes the active paragraph. All subsequent text or images will be appended to the active paragraph.

putpdf text (exp) adds content to the paragraph created by putpdf paragraph. exp may be a valid Stata expression (see [U] 13 Functions and expressions) or a normal string.

putpdf image filename embeds a portable network graphics (.png) or JPEG (.jpg) file in the paragraph. filename is the path to the image file. It may be either the full path or the relative path from the current working directory.

putpdf table tablename creates a new table that can be identified by its assigned name, tablename, for future modifications. Tables may be created in several ways:

(nrows, ncols) creates an empty table with nrows rows and ncols columns. A maximum of 50 columns in a table is allowed.

data(varlist) [if] [in] [, varnames obsno] adds the current Stata dataset in memory as a table to the active document. varlist contains a list of the variable names from the current dataset in memory. If the varnames option is specified, the first row of the table is filled with variable names. If obsno is specified, the first column of the table is filled with observation numbers. if and in may be used to restrict the data to be added to the table.

matrix(matname) [, nformat(%fmt) rownames colnames] adds a matrix called matname as a table to the active document. The elements of the matrix are formatted using %fmt. If nformat() is not specified, then %12.0g is used. If the rownames option is specified, the first column of the table is filled with matrix rownames. If the colnames option is specified, the first row of the table is filled with matrix colnames.

mata(matname) [, nformat(%fmt)] adds a Mata matrix called matname as a table to the active document. The elements of the matrix are formatted using %fmt. If nformat() is not specified, then %12.0g is used.

returnset exports a group of Stata return values to a table in the active document. It is intended primarily for use by programmers and by those who want to do further processing of their exported results in the active document.

putpdf table tablename(i,j) modifies the content and styles of the cell on the ith row and jth column in table tablename. The cell content may be a valid Stata expression, an image with supported format, or a previously created table identified by mem_tablename (usually specified with the memtable option).
Options

Options are presented under the following headings:

Options for putpdf begin
Options for putpdf paragraph
Options for putpdf text
Options for putpdf image
Options for putpdf table
    table_options
    row_col_options
    cell_options
Option for putpdf save

Options for putpdf begin

pagesize($psize$) sets the page size of the document. $psize$ may be letter, legal, A3, A4, A5, B4, or B5. The default is pagesize(letter).

landscape changes the document orientation from portrait to landscape.

font($fontname$ [$, size [$, color]]]) sets the font, font size, and font color for the document. Note that the font size and font color may be specified individually without specifying $fontname$. Use font("", size) to specify font size only. Use font("", "", color) to specify font color only. For both cases, the default font will be used.

halign($hvalue$) sets the horizontal alignment of the paragraphs, images, and tables within the document. $hvalue$ may be left, right, or center. The default is halign(left).

margin($type$, #[$unit$]) sets the page margins of the document. $type$ may be top, left, bottom, or right, which identify the location of the margin inside the document. The margin value # is measured in inches unless another $unit$ is specified. This option may be specified multiple times in a single command to account for different margin settings.

bgcolor($color$) sets the background color for the document.

Options for putpdf paragraph

font($fontname$ [$, size [$, color]])) sets the font, font size, and font color for the paragraph. Note that the font size and font color may be specified individually without specifying $fontname$. Use font("", size) to specify font size only. Use font("", "", color) to specify font color only. For both cases, the default font will be used.

Specifying font() with putpdf paragraph overrides font settings specified with putpdf begin.

halign($hvalue$) sets the horizontal alignment of the characters within the paragraph. $hvalue$ may be left, right, justified, or distribute. distribute and justified justify text between the left and right margins equally, but distribute also changes the spacing between words and characters. The default is halign(left).

valign($vvalue$) sets the vertical alignment of the characters on each line when the paragraph contains characters of varying size. $vvalue$ may be baseline, bottom, center, or top. The default is valign(baseline).

indent($indenttype$, #[$unit$]) specifies that the paragraph be indented by # units. $indenttype$ may be left, right, or para. left and right indent # units from the left or the right, respectively. para uses standard paragraph indentation and indents the first line by # inches unless another $unit$ is specified. This option may be specified multiple times in a single command to accommodate different indentation settings.
spacing\((position, \#[\text{unit}])\) sets the spacing between lines of text. \textit{position} may be \texttt{before}, \texttt{after}, or \texttt{line}. \texttt{before} specifies the space before the first line of the current paragraph, \texttt{after} specifies the space after the last line of the current paragraph, and \texttt{line} specifies the space between lines within the current paragraph. This option may be specified multiple times in a single command to accommodate different spacing settings.

bgcolor\((\text{color})\) sets the background color for the paragraph. Specifying bgcolor() with putpdf \texttt{paragraph} overrides background color specifications from putpdf \texttt{begin}.

\textbf{Options for putpdf text}

\texttt{nformat(\%fmt)} specifies the numeric format of the text when the content of the new text appended to the paragraph is a numeric value. This setting has no effect when the content is a string.

\texttt{font(fontname [, size [, color]])} sets the font, font size, and font color for the new text. Note that the font size and font color may be specified individually without specifying \texttt{fontname}. Use \texttt{font("", size)} to specify font size only. Use \texttt{font("", ",", color)} to specify font color only. For both cases, the default font will be used.

Specifying font() with putpdf \texttt{text} overrides all other font settings, including those specified with putpdf \texttt{begin} and putpdf \texttt{paragraph}.

\texttt{bold} specifies that the new text be formatted as bold.

\texttt{italic} specifies that the new text be formatted as italic.

\texttt{underline} specifies that the new text be underlined.

\texttt{strikeout} specifies that the text have a strikeout mark.

\texttt{script(sub \mid super)} changes the script style of the text. \texttt{script(sub)} makes the text a subscript. \texttt{script(sup)} makes the text a superscript.

bgcolor\((\text{color})\) sets the background color for the new text. Specifying bgcolor() with putpdf \texttt{text} overrides background color specifications from putpdf \texttt{begin} and putpdf \texttt{paragraph}.

\texttt{linebreak} specifies that a line break be added after the new text. This option may be specified multiple times to add multiple line breaks after the new text.

\textbf{Options for putpdf image}

\texttt{width(\#[\text{unit}])} sets the width of the image. If the width is larger than the body width of the document, then the body width is used. If \texttt{width()} is not specified, then the default size is used; the default is determined by the image information and the body width of the document.

\texttt{height(\#[\text{unit}])} sets the height of the image. If \texttt{height()} is not specified, then the height of the image is determined by the width and the aspect ratio of the image.

\texttt{linebreak} specifies that a line break be added after the new image. This option may be specified multiple times to add multiple line breaks after the new image.
Options for putpdf table

table_options

memtable specifies that the table be created and held in memory instead of being added to the active
document. By default, the table is added to the document immediately after it is created. This
option is useful if the table is intended to be added to a cell of another table or to be used multiple
times later.

halign(hvalue) sets the horizontal alignment of the table within the page. hvalue may be left,
right, or center. The default is halign(left).

indent(#[unit]) specifies the table indentation from the left margin of the current document.

width(#[unit | %]) and width(matname) set the table width. Any two of the types of width
specifications can be combined.

width(#[unit | %]) sets the width based on a specified value. # may be an absolute width or
a percent of the default table width, which is determined by the page width of the document. For example, width(50%) sets the table width to 50% of the default table width. The default is
width(100%).

width(matname) sets the table width based on the dimensions specified in the Stata matrix
matname, which has contents in the form of (#1, #2, ..., #n) to denote the percent of the default
table width for each column. n is the number of columns of the table, and the sum of #1 to #n
must be equal to 100.

spacing(position, #[unit]) sets the spacing before or after the table. position may be before or
after. before specifies the space before the top of the current table, and after specifies the
space after the bottom of the current table. This option may be specified multiple times in a single
command to account for different space settings.

border(bordename [, bpattern [, bcolor]]) sets the pattern and color for the specified border
of the table or a cell. This option may be specified multiple times in a single command to
accommodate different border settings.

For a table or cell, bordename may be start, end, top, bottom, or all. For a table, bordename
may also be insideH, the inside horizontal edges border, or insideV, the inside vertical edges
border.

Specifying border(start) adds a single border to the leading edge of the table or cell. Similarly,
specifying border(end), border(top), or border(bottom) adds a single border to the trailing
edge, top, or bottom of the table or cell. border(all) applies the specified pattern and color to
all borders, including the inside edges when specified for a table.

varnames specifies that the variable names be included as the first row in the table when the table
is created using the dataset in memory. By default, only the data values are added to the table.

obsno specifies that the observation numbers be included as the first column in the table when the
table is created using the dataset in memory. By default, only the data values are added to the
table.

nformat(%fmt) specifies the numeric format to be applied to the source values when creating the
table from a Stata or Mata matrix. The default is nformat(%12.0g).

rownames specifies that the row names of the Stata matrix be included as the first column in the
table. By default, only the matrix values are added to the table.

colnames specifies that the column names of the Stata matrix be included as the first row in the
table. By default, only the matrix values are added to the table.
**row_col_options**

**nosplit** specifies that row $i$ not split across pages. When displaying a table row, it is possible that a page break will fall within the contents of a cell on the row, causing the contents of that cell to be displayed across two pages. **nosplit** prevents this behavior. If the entire row cannot fit on the current page, the row will be moved to the start of the next page.

**addrows(##[, before|after])** adds $\#$ rows to the current table before or after row $i$. If **before** is specified, the rows are added before the specified row. By default, rows are added after the specified row.

**addcols(##[, before|after])** adds $\#$ columns to the current table to the right or the left of column $j$. If **before** is specified, the columns are added to the left of the specified column. By default, the columns are added after, or to the right of, the specified column.

**drop** deletes row $i$ or column $j$ from the table.

**cell_options**

**append** specifies that the new content for the cell be appended to the current content of the cell. If **append** is not specified, then the current content of the cell is replaced by the new content. Unlike with the **putdocx** command, this option with **putpdf** is used only for appending a new string to the cell when the original cell content is also a string.

**font(fontname[, size[, color]])** sets the font, font size, and font color for the text within the cell. Note that the font size and font color may be specified individually without specifying **fontname**. Use **font("", size) to specify font size only. Use **font("", ", color) to specify font color only. For both cases, the default font will be used.

**bold** specifies that the text be formatted as bold.

**italic** specifies that the text be formatted as italic.

**underline** specifies that the cell be underlined.

**strikeout** specifies that the text have a strikeout mark.

**margin(type, ##[, unit])** sets the margins inside the cell. **type** may be top, left, bottom, or right, which identify the top margin, left margin, bottom margin, or right margin of the cell, respectively. This option may be specified multiple times in a single command to account for different margin settings.

**halign(hvalue)** sets the horizontal alignment of the cell. **hvalue** may be left, right, or center. The default is **halign(left)**.

**valign(vvalue)** sets the vertical alignment of the cell. **vvalue** may be top, bottom, or center. The default is **valign(top)**.

**rowspan(#)** sets the specified cell to span vertically $\#$ cells downward. If the span exceeds the total number of rows in the table, the span stops at the last row.

**colspan(#)** sets the specified cell to span horizontally $\#$ cells to the right. If the span exceeds the total number of columns in the table, the span stops at the last column.

**span(#_1, #_2)** sets the specified cell to span $\#_1$ cells downward and span $\#_2$ cells to the right.

**bgcolor(color)** sets the background color for the cell.
Option for putpdf save

replace specifies to overwrite filename, if it exists, by the contents of the document in memory.

Remarks and examples

The putpdf command is a suite of commands used to write paragraphs, images, and tables to a PDF file. It may also be used to format each object added, with various styles. This allows you to automate exporting and formatting of, for example, Stata graphs and estimation results, and also generate various reports based on those elements.

Before we can write to a .pdf file using putpdf, we need to create a .pdf document in memory. We do this using the putpdf begin command.

. putpdf begin

Once the document is created, other objects such as paragraphs and tables may be added to it. By default, the document created uses the letter pagesize, and its layout is set to portrait. Those properties may be overwritten by specifying corresponding document options. Some other properties may also be customized; see Options for putpdf begin.

After we are done editing the document, we can save it to disk.

. putpdf save example.pdf

Note that the replace option is required if example.pdf already exists in the saving directory. If replace is specified, then all the contents in example.pdf will be overwritten.

Remaining remarks are presented under the following headings:

Add a paragraph
   Add text to paragraph
   Add an image to paragraph
Add a table
   Export data
   Export estimation results
Advanced uses

Add a paragraph

Before you can add text or an image to the paragraph, you must first begin a new paragraph by using putpdf paragraph. You can control the formatting for the whole paragraph, such as font properties and alignment, with options for putpdf paragraph. See Options for putpdf paragraph for paragraph formatting options. The current paragraph remains active until you add a new paragraph or add a table.

Add text to paragraph

Once the new paragraph is created, you add text to it by using putpdf text. The new text is appended to any text or image that has already been added to the paragraph. This text can also be formatted individually. See Options for putpdf text for text formatting options.
Example 1: Add a paragraph and format the text

Suppose we want to write a description of auto.dta to example.pdf. Our description includes the number of automobiles and the maximum miles per gallon (MPG) among all the automobiles. We can create a paragraph containing that information by using putpdf paragraph.

To start, we use the `summarize` command to get descriptive statistics for the `mpg` variable. After that, we can use the returned results from `summarize` in the text that we write. The returned results `r(N)`, `r(mean)`, and `r(max)` store the number of automobiles, the average MPG, and the maximum MPG among those automobiles.

```
. use http://www.stata-press.com/data/r15/auto
   (1978 Automobile Data)
. summarize mpg

  Variable | Obs  | Mean    | Std. Dev.  | Min | Max
----------|------|---------|------------|-----|-----
    mpg    | 74   | 21.2973 | 5.785503   | 12  | 41  
. return list
  scalars:
    r(N)    = 74
    r(sum_w) = 74
    r(mean) = 21.2972972972973
    r(Var)  = 33.47204738985561
    r(sd)   = 5.785503209735141
    r(min)  = 12
    r(max)  = 41
    r(sum)  = 1576
```

Now, we specify the command to create our document. We then add a new paragraph to the active document and append text to it. The content of each putpdf text command may be a valid Stata expression (see [U] 13 Functions and expressions) or a normal string. putpdf text can be used to break long sentences into pieces, and each piece in the paragraph can be customized to have a different style. Here, `r(max)` is formatted as bold, and `r(mean)` is formatted to have 1 decimal place.

```
. putpdf begin
. putpdf paragraph
. putpdf text ("In this dataset, there are ‘r(N)’")
. putpdf text ("models of automobiles. The maximum MPG among them is ")
. putpdf text (r(max)), bold
. putpdf text (", and the average MPG is ")
. putpdf text (r(mean)), nformat("%4.1f")
. putpdf text (".")
```

This adds text to the document that looks like this:

```
In this dataset, there are 74 models of automobiles. The maximum MPG among them is 41, and the average MPG is 21.3.
```
Add an image to paragraph

You can add any existing .png and .jpg image files to a .pdf file with putpdf image. For example, you could include a company logo. You can also add graphs from Stata output. Because Stata graphs use the .gph extension, you must use graph export to convert the Stata graph to one of the supported image formats; see [G-2] graph export.

If you are adding the image after text and you want the paragraph that contains the image to have the same format as the active paragraph, you can insert the image with no additional step. However, if you want to change the formatting or if there is no active paragraph, you must create one using putdocx paragraph. Note that you do not need to declare a new paragraph to insert an image into the cell of a table.

Example 2: Export a Stata graph

We may want to add a scatterplot showing how mileage (mpg) correlates with price (price) of cars. We can use the scatter command and then graph export to create a .png file.

```
.scatter mpg price

.graph export auto.png
```

(file auto.png written in PNG format)

Next, we use putpdf image to add the .png file to the document. Because our active paragraph is left aligned and we want our image to be centered, we declare a new paragraph.

```
.putpdf paragraph, halign(center)
.putpdf image auto.png, width(4)
```

Here, the image is put in the center of the document and is set to have a width of 4 inches. Note that the halign() option had to be specified with putpdf paragraph because alignment is controlled by paragraph settings.
Add a table

`putpdf table` is used to add a table to the document. We can edit the created table until another object such as a paragraph, another table, or a page break is added to the document. A valid table name is required to declare a table. The table name is used later as a reference to customize the table and the cells.

Export data

Exporting the data in memory is useful when you want to make a table in the `.pdf` file using content from your dataset. The `if` or `in` qualifier may be applied to export only those observations that meet the specified condition or are in the specified range (or both, if both `if` and `in` are specified).

Example 3: Export table of summary statistics

Suppose we want to export summary statistics, such as the number of automobiles, the maximum and minimum MPG, and the average MPG, that have been calculated separately for foreign and domestic automobiles. To start, we use the `statsby` command to collect the above statistics for each group. Because `statsby` creates a new dataset that overwrites the dataset in memory, we need to preserve the dataset and then restore it after we have finished exporting the data.

```
. preserve
. statsby Total=r(N) Average=r(mean) Max=r(max) Min=r(min), by(foreign):
> summarize mpg
(running summarize on estimation sample)
command:  summarize mpg
    Total:  r(N)
    Average:  r(mean)
        Max:  r(max)
        Min:  r(min)
    by:  foreign
Statsby groups
    1  2  3  4  5
```

Because we want the variable names to serve as column titles, we rename `foreign` to `Origin`. Then, we export the data in the memory as a table by specifying in `data()` the variable names `Origin`, `Total`, `Average`, `Max`, and `Min`. In this case, we use the table name `tbl1`. The order of the variable names in the list determines the column order in the table.

```
. rename foreign Origin
. putpdf table tbl1 = data("Origin Total Average Max Min"), varnames
> border(start, nil) border(end, nil) border(insideV, nil)
```

By default, the exported table includes single borders around all cells. We use the `border()` option to remove all vertical borders from the table. We can apply additional formatting to individual cells or ranges of cells; see example 4.

Example 4: Format table

The cells in the table that we created in example 3 can be further customized. For example, we can reset the contents, set the text alignment, modify the borders, and so forth. Here, we set the horizontal text of the cells on the first through the fifth columns to be right aligned instead of the default left alignment.
Our formatted tbl1 looks like this:

![Example PDF Table](image)

Afterward, we restore the dataset.

```
. restore
```

### Export estimation results

One of the primary uses of `putpdf table` is to export estimation results. Suppose we fit a linear regression model of `mpg` as a function of the car’s gear ratio (`gear_ratio`), turning radius (`turn`), and whether the car is of foreign origin (`foreign`) using `regress`. We want to add selected regression results to the document.

```
. regress mpg gear_ratio turn foreign, noheader
```

|       | Coef.  | Std. Err. | t     | P>|t| | [95% Conf. Interval] |
|-------|--------|-----------|-------|-----|---------------------|
| gear_ratio | 4.855506 | 1.522481  | 3.19  | 0.002 | 1.819013 - 7.891999 |
| turn   | -0.8364698 | 0.1440204 | -5.81 | 0.000 | -1.123709 - 0.5492302 |
| foreign | -3.503218 | 1.433526   | -2.44 | 0.017 | -6.362296 - 0.6441404 |
| _cons  | 40.865 | 8.692731   | 4.70  | 0.000 | 23.52789 - 58.2021 |

```

. return list

scalars: r(level) = 95

matrices: r(table) : 9 x 4
The displayed results returned by `regress` are saved in `r(table)`. We create the matrix `rtable` as the transpose of `r(table)` because we want to see the variable names in rows.

### Example 5: Export selected estimation results

Suppose we want to export only the point estimates and confidence intervals. The point estimates and confidence intervals in the regression table can be extracted from the matrix `rtable`. We can extract columns 1, 5, and 6 from `rtable`, combine them, and assign them to another new matrix, `r_table`.

```
. matrix r_table = rtable[1...,1], rtable[1...,5..6]
```

Then, we export `r_table` to the document as a table with the name `tbl2`.

```
. putpdf table tbl2 = matrix(r_table), nformat(%9.3f) rownames colnames
> border(start, nil) border(end, nil) border(insideH, nil) border(insideV, nil)
```

In this table, all values imported from the matrix have been formatted as %9.3f. In addition, the row and column names of the matrix `r_table` are included as the first row and first column of the table. We keep only the top and bottom borders of the table by specifying nil for the leading edge border (start), trailing edge border (end), inside horizontal edges border (insideH), and inside vertical edges border (insideV).

The column names (b, ll, and ul) from the matrix may not be exactly what we want; we can modify them by customizing the corresponding cells. We can reset the contents and the horizontal alignment of the cells on the first row to give the columns new titles.

```
. putpdf table tbl2(1,2) = ("Coef."), halign(right)
. putpdf table tbl2(1,3) = ("[95% Conf. Interval]"), halign(right) colspan(2)
```

Afterward, we add back the bottom border of the first row and right-align the cells on the rest of the rows by looping over each cell; see [P] `forvalues`.

```
. forvalues i = 1/5 {  
2.         forvalues j=1/4 {  
3.             if `i'==1 {  
4.                 putpdf table tbl2(`i','`j'), border(bottom)  
5.             }  
6.             else {  
7.                 putpdf table tbl2(`i','`j'), halign(right)  
8.             }  
9.         }  
10. }
```
Our final table appears in the document as follows:

![Table Image]

**Advanced uses**

➤ **Example 6: Create table from components**

Sometimes, we might need a table with a complicated layout. It may be difficult for us to figure out the dimension of the table and the content of each cell. In this situation, we can consider building the table in pieces and combining them. For illustrative purposes, we use the table created in example 5. The table can be considered to comprise two parts, the header and the body. We first create a table for each part.

The header part contains the column titles and is specified as a $1 \times 2$ table with borders removed and contents aligned to the right.

```
. putpdf table tbl31 = (1,2), memtable border(all, nil)
. putpdf table tbl31(1,1) = ("Coef."), halign(right)
. putpdf table tbl31(1,2) = ("[95% Conf. Interval]"), halign(right)
```

The body part contains the content that we want displayed and is created as another table using the same Stata matrix from example 5, `r_table`. Again, we remove all borders and align all contents to the right.

```
. putpdf table tbl32 = matrix(r_table), memtable border(all, nil)
> nformat(%9.3f) rownames
. forvalues i=1/4 {
  2.   forvalues j=1/4 {
  3.     putpdf table tbl32('i','j'), halign(right)
  4.   }}
  5. }
```

Notice that both tables are created with the `memtable` option, which declares that they be created in memory rather than added to the document. This is required for our next steps.
At last, we create a 2 × 1 table named tbl3, in which the first cell contains tbl31 and the second cell contains tbl32. In addition, we remove its leading edge border and trailing edge border.

```plaintext
. putpdf table tbl3 = (2,1), border(start, nil) border(end, nil)
. putpdf table tbl3(1,1) = table(tbl31)
. putpdf table tbl3(2,1) = table(tbl32)
```

This is an example of what is called a nested table.

Example 7: Create table dynamically

In the previous example, we added a table in two steps. The first step was to create a table in the document. The second step was to fill in the contents for each cell. In this process, the dimensions of the table were often predetermined. Another way to add a table is to create it dynamically: start with a simple table and then add rows or columns to it gradually.

Below we have census data recording the death rate (drate) and median age (medage) for each state. The data also record four regions of the country in which each state is located, NE, N Cntrl, South, and West. We fit a linear regression model and store the transpose of rows 1, 5, and 6 in column matrices named b, ll, and ul.

```plaintext
. use http://www.stata-press.com/data/r15/census9
(1980 Census data by state)
. regress d rate i.region medage [aw=pop], noheader
(sum of wgt is 2.2591e+08)
```

```
|     | Coef. | Std. Err. | t    | P>|t| | [95% Conf. Interval] |
|-----|-------|-----------|------|------|----------------------|
| region |      |           |      |      |                      |
| N Cntrl | .3138738 | 2.456431 | 0.13 | 0.899 | -4.633632 – 5.26138 |
| South  | -1.438452 | 2.320244 | -0.62 | 0.538 | -6.111663 – 3.234758 |
| West   | -10.90629 | 2.681349 | -4.07 | 0.000 | -16.30681 – -5.505777 |
| medage | 4.283183 | .5393329 | 7.94 | 0.000 | 3.196911 – 5.369455 |
| _cons  | -39.14727 | 17.23613 | -2.27 | 0.028 | -73.86262 – 4.431915 |
```

```plaintext
. matrix rtable = r(table)
. matrix b = rtable[1,1...]
. matrix ll = rtable[5,1...]
. matrix ul = rtable[6,1...]
```
Our goal is to collect the point estimates and confidence intervals and output a table that looks like the following:

First, we create a $1 \times 3$ table with no borders and fill the single row with Variable, Coef., and 95% C.I.. We also set the table width to be 4 inches, put the table in the center of the document, and add back the top and bottom borders.

\[
\begin{array}{ccc}
\text{Variable} & \text{Coef.} & 95\% \text{ C.I.} \\
\end{array}
\]

Afterward, we add one row to the end of the table and fill in the content of the first column in this row as region.

\[
\begin{array}{c}
\text{region} \\
\end{array}
\]

In the resulting table, the region variable has four levels, and each level takes up one row. The medage variable and the constant term take up another two rows. For each row, the first column contains the variable label, the second column contains the point estimate that is stored in the matrix \( b \), and the third column contains a formatted string of the lower limit and upper limit of the confidence intervals. Those two levels are stored in matrix \( ll \) and \( ul \), respectively.

Based on the above information, we add those rows one by one at the end of the table and fill in the content and format for each cell in the corresponding row. Notice that NE is the base level of region; its point estimate and confidence interval are replaced by Ref. and N/A in the resulting table. In addition, we reset the top and bottom borders for medage and Intercept.
Example 8: Nesting images in a table

We might want to add various images to the document and align them side by side, row by row, or both. To be more clear, we use an example to illustrate this purpose. In this example, we use another dataset—the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981).

First, we fit a three-way full factorial model of systolic blood pressure on age group, sex, and body mass index (BMI). Then, we estimate the predictive margins for each combination of agegrp and sex at levels of BMI from 10 through 40 at intervals of 10 and graph the results.

```
  use http://www.stata-press.com/data/r15/nhanes2
  . regress bpsystol agegrp##sex##c.bmi
  (output omitted)
  . forvalues v=10(10)40 {
    2.   margins agegrp, over(sex) at(bmi='v')
    3.   marginsplot
    4.   graph export bmi'v'.png
  5. }
  (output omitted)
```

Now, we want to add those four plots into the document, requiring that the margins plots for bmi=10 and bmi=20 lay side by side on top of the other two side-by-side margins plots for bmi=30 and bmi=40. It is also required that each plot have a subtitle indicating the level of BMI and that the final figure have a title. This complicated layout can be easily accomplished using `putpdf table`.

We start with a 4 × 2 table and remove all of its borders. In each cell on the odd rows, we add a plot, and we fill each cell on the even rows with the title corresponding to the plot above it and center-align the text in the cell. Finally, we add another row to the end of the table and fill it with the title for the figure.

```
  . putpdf table tbl5 = (4,2), border(all,nil)
  . putpdf table tbl5(1,1)=image(bmi10.png)
  . putpdf table tbl5(1,2)=image(bmi20.png)
  . putpdf table tbl5(2,1)=image(bmi30.png)
  . putpdf table tbl5(2,2)=image(bmi40.png)
  . putpdf table tbl5(3,1)=image(bmi10.png)
  . putpdf table tbl5(3,2)=image(bmi20.png)
  . putpdf table tbl5(4,1)=image(bmi30.png)
  . putpdf table tbl5(4,2)=image(bmi40.png)
```
This creates a table that looks like the following:

![Figure 1: Predictive margins of agegrp](image(bmi40.png))

We can now type

```
. putpdf save example.pdf
```

to save the document we that created as `example.pdf`

quietly — Quietly and noisily perform Stata command

Description

quietly suppresses all terminal output for the duration of `command`. It is useful both interactively and in programs.

noisily turns back on terminal output, if appropriate, for the duration of `command`. It is useful only in programs.

set output specifies the output to be displayed. It is useful only in programs and even then is seldom used.

Syntax

Perform command but suppress terminal output

```
quietly [ : ] command
```

Perform command and ensure terminal output

```
noisily [ : ] command
```

Specify type of output to display

```
set output { proc|inform|error }
```

Remarks and examples

Remarks are presented under the following headings:

- quietly used interactively
- quietly used in programs
- Note for programmers

quietly used interactively

Example 1

quietly is useful when you are using Stata interactively and want to temporarily suppress the terminal output. For instance, to estimate a regression of `mpg` on the variables `weight`, `foreign`, and `headroom` and to suppress the terminal output, type

```
. use http://www.stata-press.com/data/r15/auto
(1978 Automobile Data)
. quietly regress mpg weight foreign headroom
```

Admittedly, it is unlikely that you would ever want to do this in real life.
quietly used in programs

Technical note

quietly is often used in programs. Say that you have the following program to run a regression of $y$ on $x$, calculate the residuals, and then list the outliers, which are defined as points with residuals below the 5th percentile or above the 95th percentile:

```stata
program myprog
    regress '1' '2'
    predict resid, resid
    sort resid
    summarize resid, detail
    list '1' '2' resid if resid< r(p5) | resid> r(p95)
    drop resid
end
```

Although the program will work, it will also fill the screen with the regression output, any notes that predict feels obligated to mention, and the detailed output from summarize. A better version of this program might read:

```stata
program myprog
    quietly regress '1' '2'
    quietly predict resid, resid
    quietly sort resid
    quietly summarize resid, detail
    list '1' '2' resid if resid< r(p5) | resid> r(p95)
    drop resid
end
```

You can also combine quietly with {}: 

```stata
program myprog
    quietly {
        regress '1' '2'
        predict resid, resid
        sort resid
        summarize resid, detail
    }
    list '1' '2' resid if resid< r(p5) | resid> r(p95)
    drop resid
end
```

Technical note

noisily is the antonym of quietly, and it too can be used in programs and do-files. In fact, that is its only real use. We could recode our example program to read as follows:

```stata
program myprog
    quietly {
        regress '1' '2'
        predict resid, resid
        sort resid
        summarize resid, detail
        noisily list '1' '2' resid if resid< r(p5) | resid> r(p95)
        drop resid
    }
end
```

Here we have not improved readability.
Technical note

noisily is not really the antonym of quietly. If the user types quietly myprog yvar xvar, the output will be suppressed because that is what the user wants. Here a noisily inside myprog will not display the output—noisily means noisily only if the program was allowed to be noisy when it was invoked.

Technical note

If you think you understand all this, take the following test. Is there any difference between quietly do filename and run filename? How about noisily run filename and do filename? What would happen if you typed quietly noisily summarize myvar? If you typed noisily quietly summarize myvar?

When you are ready, we will tell you the answers.

quietly do filename is equivalent to run filename. Typing run is easier, however.

noisily run filename is not at all the same as do filename. run produces no output, and no matter how noisily you run run, it is still quiet.

Typing quietly noisily summarize myvar is the same as typing summarize myvar. Think of it as quietly {noisily summarize myvar}. It is the inside noisily that takes precedence.

Typing noisily quietly summarize myvar is the same as typing quietly summarize myvar—it does nothing but burn computer time. Again it is the inside term, quietly this time, that takes precedence.

Technical note

set output proc means that all output, including procedure (command) output, is displayed. inform suppresses procedure output but displays informative messages and error messages. error suppresses all output except error messages. In practice, set output is seldom used.

Note for programmers

If you write a program or ado-file, say, mycmd, there is nothing special you need to do so that your command can be prefixed with quietly. That said, c-class value c(noisily) (see [P] creturn) will return 0 if output is being suppressed and 1 otherwise. Thus your program might read

```
program mycmd
    ... display ... display ...
    ... end
```
or

    program mycmd
    ...
    if c(noisily) {
        display ...
        display ...
    }
    ...
    end

The first style is preferred. If the user executes `quietly mycmd`, the output from `display` itself, along with the output of all other commands, will be automatically suppressed.

If the program must work substantially to produce what is being displayed, however, and the only reason for doing that work is because of the display, then the second style is preferred. In such cases, you can include the extra work within the block of code executed only when `c(noisily)` is true and thus make your program execute more quickly when it is invoked `quietly`.

Also see

[P] `capture` — Capture return code
[U] 18 Programming Stata
**Description**

_return_ sets aside and restores the contents of $r()$.

_return hold_ stores under _name_ the contents of $r()$ and clears $r()$. If _name_ is a name obtained from _tempname_, _name_ will be dropped automatically at the program’s conclusion, if it is not automatically or explicitly dropped before that.

_return restore_ restores from _name_ the contents of $r()$ and, unless option hold is specified, drops _name_.

_return drop_ removes from memory (drops) _name_ or, if _all_ is specified, all _return_ names currently saved.

_return dir_ lists the names currently set aside by _return_.

**Syntax**

Set aside contents of $r()$

```
_return hold name
```

Restore contents of $r()$ from _name_

```
_return restore name [ , hold ]
```

Drop specified _return name_

```
_return drop {name | _all}
```

List names currently stored by _return_

```
_return dir
```

**Option**

hold, specified with _return restore_, specifies that results continue to be held so that they can be _return restored_ later, as well. If the option is not specified, the specified results are restored and _name_ is dropped.
Remarks and examples

_return_ is rarely necessary. Most programs open with

```
program example
    version 15.0
    syntax ...
    marksample touse
    if "'exp'")' != "'{
        touse e
        qui generate double 'e' = 'exp' if 'touse'
    }
    ... (code to calculate final results) ...
end
```

In the program above, no commands are given that change the contents of _r()_ until all parsing is complete and the if _exp_ and _=exp_ are evaluated. Thus the user can type

```
. summarize myvar
. example ... if myvar>r(mean) ...
```

and the results will be as the user expects.

Some programs, however, have nonstandard and complicated syntax, and in the process of deciphering that syntax, other _r-_class commands might be run before the user-specified expressions are evaluated. Consider a command that reads

```
program example2
    version 15.0
    ... (commands that parse) ...
    ... (r() might be reset at this stage) ...
    ... commands that evaluate user-specified expressions ...
    tempvar touse
    mark 'touse' 'if'
    tempvar v1 v2
generate double 'v1' = 'exp1' if 'touse'
    // 'exp1' specified by user
generate double 'v2' = 'exp2' if 'touse'
    // 'exp2' specified by user
    ... (code to calculate final results) ...
end
```

Here it would be a disaster if the user typed

```
. summarize myvar
. example2 ... if myvar>r(mean) ...
```

because _r(mean)_ would not mean what the user expected it to mean, which is the mean of _myvar_. The solution to this problem is to code the following:
return — Preserve stored results

```stata
program example2
    version 15.0
    // hold on to r()
    tempname myr
    _return hold 'myr'
    ...(commands that parse)...  
    ...(r()) might be reset at this stage)...  
    ... commands that evaluate user-specified expressions...  
    // restore r()
    _return restore 'myr'
    tempvar touse
    mark 'touse' 'if'
    tempvar v1 v2
    generate double 'v1' = 'exp1' if 'touse'  
    // 'exp1' specified by user
    generate double 'v2' = 'exp2' if 'touse'  
    // 'exp2' specified by user
    ...(code to calculate final results)...  
end
```

In the above example, we hold on to the contents of r() in ‘myr’ and then later bring them back.

Stored results

_return restore restores in r() those results that were stored in r() when _return hold was executed.

Also see

[P] return — Return stored results
Description

Results of calculations are stored by many Stata commands so that they can be easily accessed and substituted into subsequent commands. This entry summarizes for programmers how to store results. If your interest is in using previously stored results, see [R] stored results.

return stores results in r().
ereturn stores results in e().
sreturn stores results in s().

Stata also has the values of system parameters and certain constants such as pi stored in c(). Because these values may be referred to but not assigned, the c-class is discussed in a different entry; see [P] creturn.

Syntax

Return results for general commands, stored in r()

return list [, all]
return clear
return scalar name = exp
return local name = exp
return local name ["]string[""]
return matrix name [=] matname [, copy]
return add
Return results for estimation commands, stored in e()

```
ereturn list [ , all]
ereturn clear
ereturn post [ b [ V [ Cns]]] [ weight] [ , depname(string) obs(#) dof(#)
esample(varname) properties(string)]
ereturn scalar name = exp
ereturn local name = exp
ereturn local name ["string"]
ereturn matrix name [ =] matname [ , copy]
ereturn repost [ b = b] [ V = V] [ Cns = Cns] [ weight] [ , esample(varname)
properties(string) rename]
```

Return results for parsing commands, stored in s()

```
sreturn list
sreturn clear
sreturn local name = exp
sreturn local name ["string"]
```

where b, V, and Cns are *matnames*, which is the name of an existing matrix.

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

**Options**

all is for use with return list and ereturn list. all specifies that hidden and historical stored results be listed along with the usual stored results. This option is seldom used. See *Using hidden and historical stored results* and *Programming hidden and historical stored results* in Remarks and examples for more information. These sections are written in terms of `return list`, but everything said there applies equally to `ereturn list`. all is not allowed with sreturn list because s() does not allow hidden or historical results.

copy specified with return matrix or ereturn matrix indicates that the matrix is to be copied; that is, the original matrix should be left in place. The default is to “steal” or “rename” the existing matrix, which is fast and conserves memory.

depname(string) is for use with ereturn post. It supplies the name of the dependent variable to appear in the estimation output. The name specified need not be the name of an existing variable.
obs(#) is for use with \texttt{ereturn post}. It specifies the number of observations on which the estimation was performed. This number is stored in \texttt{e(N)}, and \texttt{obs()} is provided simply for convenience. Results are no different from those for \texttt{ereturn post} followed by \texttt{ereturn scalar N = #}.

dof(#) is for use with \texttt{ereturn post}. It specifies the number of denominator degrees of freedom to be used with \texttt{t} and \texttt{F} statistics and so is used in calculating significance levels and confidence intervals. The number specified is stored in \texttt{e(df\_r)}, and \texttt{dof()} is provided simply for convenience. Results are no different from those for \texttt{ereturn post} followed by \texttt{ereturn scalar df\_r = #}.

esample(\texttt{varname}) is for use with \texttt{ereturn post} and \texttt{ereturn repost}. It specifies the name of a 0/1 variable that is to become the \texttt{e(sample)} function. \texttt{varname} must contain 0 and 1 values only, with 1 indicating that the observation is in the estimation subsample. \texttt{ereturn post} and \texttt{ereturn repost} will be able to execute a little more quickly if \texttt{varname} is stored as a byte variable.

\texttt{varname} is dropped from the dataset, or more correctly, it is stolen and stashed in a secret place.

\texttt{properties(string)} specified with \texttt{ereturn post} or \texttt{ereturn repost} sets the \texttt{e(properties)} macro. By default, \texttt{e(properties)} is set to \texttt{b V} if \texttt{properties()} is not specified.

\texttt{rename} is for use with the \texttt{b = b} syntax of \texttt{ereturn repost}. All numeric estimation results remain unchanged, but the labels of \texttt{b} are substituted for the variable and equation names of the already posted results.

\section*{Remarks and examples}

Remarks are presented under the following headings:

\begin{itemize}
  \item \textit{Introduction}
  \item Storing results in \texttt{r()}
  \item Storing results in \texttt{e()}
  \item Storing results in \texttt{s()}
  \item Recommended names for stored results
  \item Using hidden and historical stored results
  \item Programming hidden and historical stored results
\end{itemize}

\section*{Introduction}

This entry summarizes information that is presented in greater detail in other parts of the Stata documentation. Most particularly, we recommend that you read \texttt{[U] 18 Programming Stata}. The commands listed above are used by programmers to store results, which are accessed by others using \texttt{r()}, \texttt{e()}, and \texttt{s()}; see \texttt{[R] stored results}.

The commands listed above may be used only in programs—see \texttt{[U] 18 Programming Stata} and \texttt{[P] program}—and then only when the program is declared explicitly as being \texttt{rclass}, \texttt{eclass}, or \texttt{sclass}:

\begin{verbatim}
program ..., rclass
  ...
return ...
  ...
end

program ..., eclass
  ...
ereturn ...
  ...
end
\end{verbatim}
Storing results in r()

- The program must be declared explicitly to be r-class: `program ... , rclass`.
- Distinguish between r() (returned results) and return() (results being assembled that will be returned). The program you write actually stores results in return(). Then when your program completes, whatever is in return() is copied to r(). Thus the program you write can consume r() results from other programs, and there is no conflict.
- return clear clears the return() class. This command is seldom used because return() starts out empty when your program begins. return clear is for those instances when you have started assembling results and all is going well, but given the problem at hand, you need to start all over again.
- return scalar name = exp evaluates exp and stores the result in the scalar return(name). exp must evaluate to a numeric result or missing. If your code has previously stored something in return(name), whether a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.
- return local name = exp evaluates exp and stores the result in the macro return(name). exp may evaluate to a numeric or string result. If your code has previously stored something in return(name), whether a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.

Be careful with this syntax: do not code
```
return local name = ‘mymacro’
```
because that will copy just the first 2045 characters of ‘mymacro’. Instead, code
```
return local name = “‘mymacro’”
```
- return local name string copies string to macro return(name). If your code has previously stored something in return(name), whether a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.

If you do not enclose string in double quotes, multiple blanks in string are compressed into single blanks.
- return matrix name matname destructively copies matname into matrix return(name), meaning that matname is erased (matname is renamed return(name)). If your code has previously stored something in return(name), whether a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.
- return add copies everything new in r() into return(). Say that your program performed a summarize. return add lets you add everything just returned by summarize to the to-be-return results of your program. If your program had already set return(N), summarize’s r(N) would not replace the previously set result. The remaining r() results set by summarize would be copied.
Storing results in e()

For detailed guidance on storing in e(), see [P] ereturn. What follows is a summary.

- The program must be declared explicitly to be e-class: `program ... eclass`.
- The e-class is cleared whenever an `ereturn post` is executed. The e-class is a static, single-level class, meaning that results are posted to the class the instant that they are stored.
- `ereturn clear` clears e(). This is a rarely used command.
- `ereturn post` is how you must begin storing results in e(). Because `ereturn post` clears e(), anything stored in e() prior to the `ereturn post` is lost.

`ereturn post` stores matrix (vector, really) e(b), matrices e(V) and e(Cns), weight-related macros e(wtype) and e(wexp), and function e(sample). The most common syntax is

```
ereturn post 'b' 'V', esample('touse') ...
```

where ‘b’ is a row vector containing the parameter estimates, ‘V’ is a symmetric matrix containing the variance estimates, and ‘touse’ is a 0/1 variable recording 1 in observations that appear in the estimation subsample.

The result of this command will be that ‘b’, ‘V’, and ‘touse’ all disappear. In fact, `ereturn post` examines what you specify and, if it is satisfied with them, renames them e(b), e(V), and e(sample).

For more advanced usage that also posts constraint and weight information, see [P] ereturn.

In terms of `ereturn post`’s other options,

- We recommend that you specify `depname(string)` if there is one dependent variable name that you want to appear on the output. Whether you specify `depname()` or not, remember later to define macro e(depvar) to contain the names of the dependent variables.
- Specify `obs(#)`, or remember later to define scalar e(N) to contain the number of observations.
- Few models require specifying `dof(#)`, or, if that is not done, remembering to later define scalar e(df_r). This all has to do with substituting t and F statistics on the basis of # (denominator) degrees of freedom for asymptotic z and $\chi^2$ statistics in the estimation output.

- `ereturn scalar name = exp` evaluates exp and stores the result in the scalar e(name). exp must evaluate to a numeric result or missing. If your code has previously stored something in e(name), whether that be a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.
- `ereturn local name = exp` evaluates exp and stores the result in the macro e(name). exp may evaluate to a numeric or string result. If your code has previously stored something in e(name), whether that be a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.

Be careful with this syntax: do not code

```
ereturn local name = 'mymacro'
```

because that will copy just the first 2045 characters of ‘mymacro’. Instead, code

```
ereturn local name = "'mymacro'"
```

- `ereturn local name string` copies string to macro e(name). If your code has previously stored something in e(name), whether a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it.
If you do not enclose *string* in double quotes, multiple blanks in *string* are compressed into single blanks.

- **ereturn matrix name = matname** destructively copies *matname* into matrix *e(name)*, meaning that *matname* is erased. At least, that is what happens if you do not specify the *copy* option. What actually occurs is that *matname* is renamed *e(name)*. If your code has previously stored something in *e(name)*, whether a scalar, matrix, or whatever else, the previous value is discarded and this result replaces it, with two exceptions:

  **ereturn matrix** cannot be used to store in *e(b)* or *e(V)*. The only way to post matrices to these special names is to use **ereturn post** and **ereturn repost** so that various tests can be run on them before they are made official. Other Stata commands use *e(b)* and *e(V)* and expect to see a valid estimation result. If *e(b)* is $1 \times k$, they expect *e(V)* to be $k \times k$. They expect that the names of rows and columns will be the same so that the $i$th column of *e(b)* corresponds to the $i$th row and column of *e(V)*. They expect *e(V)* to be symmetric. They expect *e(V)* to have positive or zero elements along its diagonal, and so on. **ereturn post** and **ereturn repost** check these assumptions.

- **ereturn repost** allows changing *e(b)*, *e(V)*, *e(Cns)*, *e(wtype)*, *e(wexp)*, *e(properties)*, and *e(sample)* without clearing the estimation results and starting all over again. As with **ereturn post**, specified matrices and variables disappear after reposting because they are renamed *e(b)*, *e(V)*, *e(Cns)*, or *e(sample)* as appropriate.

- Programmers posting estimation results should remember to store
  a. Macro *e(cmd)*, containing the name of the estimation command. Make this the last thing you store in *e()*.
  b. Macro *e(cmdline)*, containing the command the user typed.
  c. Macro *e(depvar)*, containing the names of the dependent variables.
  d. Scalar *e(N)*, containing the number of observations.
  e. Scalar *e(df_m)*, containing the model degrees of freedom.
  f. Scalar *e(df_r)*, containing the denominator degrees of freedom if estimates are nonasymptotic; otherwise, do not define this result.
  g. Scalar *e(ll)*, containing the log-likelihood value, if relevant.
  h. Scalar *e(ll_0)*, containing the log-likelihood value for the constant-only model, if relevant.
  i. Scalar *e(chi2)*, containing the $\chi^2$ test of the model against the constant-only model, if relevant.
  j. Macro *e(chi2type)*, containing LR, Wald, or other, depending on how *e(chi2)* was obtained.
  k. Scalar *e(r2)*, containing the value of the $R^2$ if it is calculated.
  l. Scalar *e(r2_p)*, containing the value of the pseudo-$R^2$ if it is calculated.
  m. Macro *e(vce)*, containing the name of the *vcetype* that was specified in the *vce()* option; see [R] vce_option.
  n. Macro *e(vcetype)*, containing the text to appear above standard errors in estimation output, typically Robust, or it is undefined.
  o. Macro *e(clustvar)*, containing the name of the cluster variable, if any.
  p. Scalar *e(N_clust)*, containing the number of clusters.
  q. Scalar *e(rank)*, containing the rank of *e(V)*.
  r. Macro *e(predict)*, containing the name of the command that *predict* is to use; if this is blank, *predict* uses the default _predict.
s. Macro `e(estat_cmd)`, containing the name of an `estat` handler program if you wish to customize the behavior of `estat`.

t. Macro `e(properties)`, containing properties of the estimation command, typically `b V`, indicating that the command produces a legitimate coefficient vector and VCE matrix.

### Storing results in `s()`

- The program must be declared explicitly to be s-class: `program ... , sclass`.
- The s-class is not cleared automatically. It is a static, single-level class. Results are posted to `s()` the instant they are stored.
- `sreturn clear` clears `s()`. We recommend that you use this command near the top of s-class routines. `sreturn clear` may be used in non–s-class programs, too.
- The s-class provides macros only and is intended for returning results of subroutines that parse input. At the parsing step, it is important that the r-class not be changed or cleared because some of what still awaits being parsed might refer to `r()`, and the user expects those results to substitute according to what was in `r()` when he or she typed the command.
- `sreturn local name = exp` evaluates `exp` and stores the result in the macro `s(name)`. `exp` may evaluate to a numeric or string result. If your code has previously stored something else in `s(name)`, the previous value is discarded and this result replaces it.

Be careful with this syntax: do not code

```
sreturn local name = 'mymacro'
```

because that will copy just the first 2045 characters of `'mymacro'`. Instead, code

```
sreturn local name = "'mymacro'"
```

- `sreturn local name string` copies `string` to macro `s(name)`. If your code has previously stored something else in `s(name)`, the previous value is discarded and this result replaces it.

If you do not enclose `string` in double quotes, multiple blanks in `string` are compressed into single blanks.

### Recommended names for stored results

Users will appreciate it if you use predictable names for your stored results. We use these rules:

- Mathematical and statistical concepts such as number of observations and degrees of freedom are given short mathematical-style names. Subscripting is indicated with `\_`. Names are to proceed from the general to the specific. If `N` means number of observations, `N\_1` might be the number of observations in the first group.

Suffixes are to be avoided where possible. For instance, a $\chi^2$ statistic would be recorded in a variable starting with `chi2`. If, in the context of the command, a statement about “the $\chi^2$ statistic” would be understood as referring to this statistic, then the name would be `chi2`. If it required further modification, such as $\chi^2$ for the comparison test, then the name might be `chi2\_c`. 

Common prefixes are

- N: number of observations
- df: degrees of freedom
- k: count of parameters
- n: generic count
- lb and ub: lower and upper bound of confidence interval
- chi2: $\chi^2$ statistic
- t: t statistic
- F: $F$ statistic
- p: significance
- p and pr: probability
- ll: log likelihood
- D: deviance
- r2: $R^2$

- Programming concepts, such as lists of variable names, are given English-style names. Names should proceed from the specific to the general. The name of the dependent variable is `depvar`, not `vardep`.

Some examples are

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>depvar</td>
<td>dependent variable names</td>
</tr>
<tr>
<td>eqnames</td>
<td>equation names</td>
</tr>
<tr>
<td>model</td>
<td>name of model fit</td>
</tr>
<tr>
<td>xvar</td>
<td>$x$ variable</td>
</tr>
<tr>
<td>title</td>
<td>title used</td>
</tr>
</tbody>
</table>

- Popular usage takes precedence over the rules. For example:
  a. `mss` is model sum of squares, even though, per the first rule of this section, it ought to be `ss_m`.
  b. `mean` is used as the prefix to record means.
  c. `Var` is used as the prefix to mean variance.
  d. The returned results from most Stata commands follow this rule.

### Using hidden and historical stored results

Most results stored in `r()` and `e()` are visible—type `return list`. Sometimes, other stored results exist, too. For instance, consider the Stata command `summarize`. Let's pretend that in addition to everything that `summarize` stores in `r()`—you know about `r(N)`, `r(mean)`, `r(sd)`, etc.—`summarize` also stores `r(secret)` and `r(sigma)`. `summarize` does not do this, but pretend that it did. If `summarize` stored `r(secret)` as hidden and `r(sigma)` as historical, you would not know they existed from the output of `return list` unless you typed `return list, all`. If you typed that command, you would discover `r(secret)` and `r(sigma)`, and you might learn from the output that `r(secret)` was hidden whereas `r(sigma)` was historical. The output is trying to tell you 1) the two stored results exist, 2) you may use them just as you use any other stored result, and 3) the reason why the two stored results were not listed by default.

There are two reasons why `summarize` might not store results so that you can see them when you type `return list`.

The first reason is that `summarize` is designed to work tightly with some other Stata subroutine and is using `r()` to pass complicated information. The information that is stored is so arcane that you would not want to read documentation about it. Stata puts such stored results into the hidden category where you will not see them by default. If you type `return list, all` and find hidden
stored results, we recommend that you do not use their contents in your own do- and ado-files. Because hidden stored results are not documented, their names, contents, and even their existence could change in future releases.

The other reason summarize might omit a stored result from return list concerns backward compatibility. Assume that for Stata 4, summarize stored the standard deviation in \texttt{r(sigma)} instead of \texttt{r(sd)}. Assume that the editors at StataCorp decided later that \texttt{r(sd)} would be a better name. The programmers at StataCorp could not simply change the name from \texttt{r(sigma)} to \texttt{r(sd)}, because users might have already written do- or ado-files before the change. Changing the name could break old do- and ado-files, and it is a hallmark of Stata that your code will continue to work regardless of how long ago users wrote it. Thus the programmers at StataCorp could choose to store the standard deviation in both \texttt{r(sigma)} and \texttt{r(sd)} in all cases, or they could store the standard deviation in \texttt{r(sd)} and store it in \texttt{r(sigma)} only when the old do- or ado-file explicitly included a version 4 or earlier statement. Either way, \texttt{r(sigma)} is of no interest to modern Stata users, and so the programmers mark \texttt{r(sigma)} as historical. Now when you type \texttt{return list}, you will not see \texttt{r(sigma)} mentioned; and when you type \texttt{return list, all}, you will see \texttt{r(sigma)} listed, and you are told that it was not mentioned earlier as being historical.

Typing \texttt{return list, all} can be useful when you are debugging or adding new features to an old program and want to see the historical stored results to better understand your old program.

What was just said about \texttt{r()} and return list applies equally to \texttt{e()} and ereturn list, and it applies equally to user-written additions to Stata and to official Stata commands. That’s the story of all.

Programmers wishing to exploit the hidden and historical markings in their own programs should see the next section.

**Programming hidden and historical stored results**

You can mark stored results as hidden or historical by specifying the optional \texttt{hcat} argument with the appropriate return or ereturn command:

```stata
return [hcat] scalar name = exp
return [hcat] local name = exp
return [hcat] local name [“]string[“]
return [hcat] matrix name [=] matname [, copy]

ereturn [hcat] scalar name = exp
ereturn [hcat] local name = exp
ereturn [hcat] local name [“]string[“]
ereturn [hcat] matrix name [=] matname [, copy]
```

\texttt{hcat} specifies the hiddenness of the result and may be

- \texttt{visible}
- \texttt{hidden}
- \texttt{historical[relno]}

where \texttt{relno} is \#\#\#\# . \#\#\#\#\# such as 2, 10, 10., 10.1, or 10.12. \texttt{visible} is the default when \texttt{hcat} is not specified.
Thus if you are writing an r-class command and wish to store $r(\text{private})$ as a hidden scalar, you can code

```plaintext
return hidden scalar private = ...
```

If you wish to store $r(\text{lastvar})$ as a hidden local, you can code

```plaintext
return hidden local lastvar "...
```

If you wanted $r(\text{lastvar})$ to be historical rather than hidden, you would code

```plaintext
return historical local lastvar "...
```

If you wanted $r(\text{lastvar})$ to be historical as of Stata 15, meaning that $r(\text{lastvar})$ was current up to but not including Stata 15, you would code

```plaintext
return historical(15) local lastvar "...
```

If you wish to create $r(X)$ as a hidden matrix, you can code

```plaintext
return hidden matrix X = ...
```

All the above examples could be performed using `ereturn` instead of `return`. They could not be performed using `sreturn` because `s()` does not allow hidden or historical results.

[U] 18 Programming Stata

[U] 18.10 Storing results
Description

_rmcoll returns in r(varlist) an updated version of varlist that is specific to the sample identified by if, in, and any missing values in varlist. _rmcoll flags variables that are to be omitted because of collinearity. If varlist contains factor variables, then _rmcoll also enumerates the levels of factor variables, identifies the base levels of factor variables, and identifies empty cells in interactions.

The following message is displayed for each variable that _rmcoll flags as omitted because of collinearity:

```
note: ______ omitted because of collinearity
```

The following message is displayed for each empty cell of an interaction that _rmcoll encounters:

```
note: ______ identifies no observations in the sample
```

_ml users: it is not necessary to call _rmcoll because ml flags collinear variables for you, assuming that you do not specify ml model’s collinear option. Even so, ml programmers sometimes use _rmcoll because they need the sample-specific set of variables, and in such cases, they specify ml model’s collinear option so that ml does not waste time looking for collinearity again. See [R] ml.

_rmdcoll performs the same task as _rmcoll and checks that depvar is not collinear with the variables in indepvars. If depvar is collinear with any of the variables in indepvars, then _rmdcoll reports the following message with the 459 error code:

```
______ collinear with ______
```

Syntax

Identify variables to be omitted because of collinearity

```
_rmcoll varlist [if] [in] [weight] [, noconstant collinear expand forcedrop]
```

Identify independent variables to be omitted because of collinearity

```
_rmdcoll depvar indepvars [if] [in] [weight] [, noconstant collinear expand normcoll]
```

varlist and indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

varlist, depvar, and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
Options

noconstant specifies that, in looking for collinearity, an intercept not be included. That is, a variable that contains the same nonzero value in every observation should not be considered collinear.

collinear specifies that collinear variables not be flagged.

expand specifies that the expanded, level-specific variables be posted to r(varlist). This option will have an effect only if there are factor variables in the variable list.

forcedrop specifies that collinear variables be dropped from the variable list instead of being flagged. This option is not allowed when the variable list already contains flagged variables, factor variables, or interactions.

normcoll specifies that collinear variables have already been flagged in indepvars. Otherwise, _rmcoll is called first to flag any such collinearity.

Remarks and examples

_rmcoll and _rmdcoll are typically used when writing estimation commands.

_rmcoll is used if the programmer wants to flag the collinear variables from the independent variables.

_rmdcoll is used if the programmer wants to detect collinearity of the dependent variable with the independent variables.

Example 1: Flagging variables because of collinearity

Let’s load auto.dta and add a variable called tt that is collinear with variables turn and trunk. The easiest way to do this is to generate tt as the sum of turn and trunk.

. use http://www.stata-press.com/data/r15/auto
  (1978 Automobile Data)
. generate tt = turn + trunk

Now we can use _rmcoll to identify that we have a collinearity and flag a variable because of it.

. _rmcoll turn trunk tt
  note: tt omitted because of collinearity
. display r(varlist)
  turn trunk o.tt

_rmcoll reported that tt was being flagged because of collinearity and attached the omit operator to tt resulting in “o.tt” being returned in r(varlist).

Example 2: Factor variables

_rmcoll works with factor variables. Let’s pass rep78 as a factor variable to _rmcoll.

. _rmcoll i.rep78
. display r(varlist)
i(1 2 3 4 5)b1.rep78
The updated variable list now contains the enumerated levels of `rep78` and identifies its base level. Use the `expand` option if you want to be able to loop over the level-specific, individual variables in `r(varlist)`.  

```
._rmcoll i.rep78, expand
.display r(varlist)
1b.rep78 2.rep78 3.rep78 4.rep78 5.rep78
```

### Example 3: Interactions

`_rmcoll` works with interactions and reports when it encounters empty cells. An empty cell is a combination of factor levels that does not occur in the dataset. Let’s use the `table` command with factor variables `rep78` and `foreign` to see that there are two empty cells:

```
.table rep78 foreign
```

<table>
<thead>
<tr>
<th>Repair Record</th>
<th>Car type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1978</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>27</td>
</tr>
<tr>
<td>4</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
</tr>
</tbody>
</table>

Now let’s pass the interaction of factor variables `rep78` and `foreign` to `_rmcoll`.

```
._rmcoll rep78#foreign
.note: 1.rep78#1.foreign identifies no observations in the sample
.note: 2.rep78#1.foreign identifies no observations in the sample
.display r(varlist)
1b.rep78#0b.foreign 1b.rep78#1o.foreign 2.rep78#0b.foreign 2o.rep78#1o.foreign
> 3.rep78#0b.foreign 3.rep78#1.foreign 4.rep78#0b.foreign 4.rep78#1.foreign
> 5.rep78#0b.foreign 5.rep78#1.foreign
```

### Example 4: Coding fragment for standard variables

A code fragment for a program that uses `_rmcoll` might read

```
...  
syntax varlist [fweight iweight] ... [ , noCONstant ... ]
marksample touse
if "weight" != "" {
  tempvar w
  quietly generate double 'w' = 'exp' if 'touse'
  local wgt ['weight'=w']
}
else local wgt /* is nothing */
gettoken depvar xvars : varlist
._rmcoll 'xvars' 'wgt' if 'touse', 'constant'
local xvars 'r(varlist)'  
...  
```
In this code fragment, `varlist` contains one dependent variable and zero or more independent variables. The dependent variable is split off and stored in the local macro `depvar`. Then the remaining variables are passed through `_rmcoll`, and the resulting updated independent variable list is stored in the local macro `xvars`.

**Example 5: Coding fragment for factor variables and time-series operators**

Here we modified the above code fragment to allow for factor variables and time-series operators.

```stata
... syntax varlist(fv ts) [fweight iweight] ... [, noCONStant ... ]
marksample touse
if "weight" != "" {
    tempvar w
    quietly generate double `w' = `exp' if `touse'
    local wgt ['weight'='`w']
} else local wgt /* is nothing */
gettoken depvar xvars : varlist
   _rmcoll `xvars' `wgt' if `touse', expand 'constant'
local xvars `r(varlist)'
... 
```

The `varlist` argument in the `syntax` command contains the `fv` specifier to allow factor variables and the `ts` specifier to allow time-series operators. We also added the `expand` option in case the remaining code needs to loop over the level-specific, individual variables in the `xvars` macro.

**Stored results**

`_rmcoll` and `_rmdcoll` store the following in `r()`:

- Scalars: `r(k_omitted)` number of omitted variables in `r(varlist)`
- Macros: `r(varlist)` the flagged and expanded variable list

Title

**rmsg — Return messages**

Description

`set rmsg` determines whether the return message is to be displayed at the completion of each command. The initial setting is `off`. The return message shows how long the command took to execute and what time it completed execution.

Syntax

```
set rmsg {on|off} [, permanently ]
```

Option

`permanently` specifies that, in addition to making the change right now, the `rmsg` setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

[U] 8 Error messages and return codes
Description

_robust_ helps implement estimation commands and is rarely used. That is because other commands are implemented in terms of it and are easier and more convenient to use. For instance, if all you want to do is make your estimation command allow the `vce(robust)` and `vce(cluster clustvar)` options, see [R] _ml_. If you want to make your estimation command work with survey data, it is easier to make your command work with the _svy_ prefix—see [P] _program properties_—rather than to use _robust_.

If you really want to understand what _ml_ and _svy_ are doing, however, this is the section for you. Or, if you have an estimation problem that does not fit with the _ml_ or _svy_ framework, then _robust_ may be able to help.

_robust_ is a programmer’s command that computes a robust variance estimator based on _varlist_ of equation-level scores and a covariance matrix. It produces estimators for ordinary data (each observation independent), clustered data (data not independent within groups, but independent across groups), and complex survey data from one stage of stratified cluster sampling.

The robust variance estimator goes by many names: Huber/White/sandwich are typically used in the context of robustness against heteroskedasticity. Survey statisticians often refer to this variance calculation as a first-order Taylor-series linearization method. Despite the different names, the estimator is the same.

The equation-level score variables (_varlist_) consist of one variable for single-equation models or multiple variables for multiple-equation models, one variable for each equation. The “covariance” matrix before adjustment is either posted using _ereturn post_ (see [P] _ereturn_) or specified with the _variance(matname)_ option. In the former case, _robust_ replaces the covariance in the post with the robust covariance matrix. In the latter case, the matrix _matname_ is overwritten with the robust covariance matrix. Note: The robust covariance formula is _V = DMD_, where _D_ is what we are calling the “covariance” matrix before adjustment; this is not always a true covariance. See _Remarks and examples_ below.

Before reading this section, you should be familiar with [U] _20.22 Obtaining robust variance estimates_ and the _Methods and formulas_ section of [R] _regress_. We assume that you have already programmed an estimator in Stata and now wish to have it compute robust variance estimates. If you have not yet programmed your estimator, see [U] _18 Programming Stata_, [R] _ml_, and [P] _ereturn_.

If you wish to program an estimator for survey data, then you should write the estimator for nonsurvey data first and then use the instructions in [P] _program properties_ (making programs _svyable_) to get your estimation command to work properly with the _svy_ prefix. See [SVY] _variance estimation_ for a discussion of variance estimation for survey data.
Syntax

```

included in the computation. If **zeroweight** is not specified (the default), observations with zero weights are omitted. Including the observations with zero weights affects the computation in that it may change the counts of PSUs (clusters) per stratum. Stata’s svy prefix command includes observations with zero weights; all other commands exclude them. This option is typically used only with survey data.

### Remarks and examples

Remarks are presented under the following headings:

- **Introduction**
- **Clustered data**
- **Survey data**
- **Controlling the header display**
- **Maximum likelihood estimators**
- **Multiple-equation estimators**

#### Introduction

This section explains the formulas behind the robust variance estimator and how to use **_robust** through an informal development with some simple examples. For an alternative discussion, see [U] 20.22 Obtaining robust variance estimates. See the references cited at the end of this entry for more formal expositions.

First, consider ordinary least-squares regression. The estimator for the coefficients is

$$\hat{\beta} = (X'X)^{-1}X'y$$

where $y$ is an $n \times 1$ vector representing the dependent variable and $X$ is an $n \times k$ matrix of covariates.

Because everything is considered conditional on $X$, $(X'X)^{-1}$ can be regarded as a constant matrix. Hence, the variance of $\hat{\beta}$ is

$$V(\hat{\beta}) = (X'X)^{-1} V(X'y) (X'X)^{-1}$$

What is the variance of $X'y$, a $k \times 1$ vector? Look at its first element; it is

$$X'_1y = x_{11}y_1 + x_{21}y_2 + \cdots + x_{n1}y_n$$

where $X_1$ is the first column of $X$. Because $X$ is treated as a constant, you can write the variance as

$$V(X'_1y) = x_{11}^2 V(y_1) + x_{21}^2 V(y_2) + \cdots + x_{n1}^2 V(y_n)$$

The only assumption made here is that the $y_j$ are independent.

The obvious estimate for $V(y_j)$ is $\hat{e}_j^2$, the square of the residual $\hat{e}_j = y_j - x_j\hat{\beta}$, where $x_j$ is the $j$th row of $X$. You must estimate the off-diagonal terms of the covariance matrix for $X'y$, as well. Working this out, you have

$$\hat{V}(X'y) = \sum_{j=1}^{n} \hat{e}_j^2 x'_jx_j$$

$x_j$ is defined as a row vector so that $x'_jx_j$ is a $k \times k$ matrix.
You have just derived the robust variance estimator for linear regression coefficient estimates for independent observations:

\[ \hat{V}(\hat{\beta}) = (X'X)^{-1} \left( \sum_{j=1}^{n} \hat{e}_j^2 x'_j x_j \right) (X'X)^{-1} \]

You can see why it is called the sandwich estimator.

### Technical note

The only detail not discussed is the multiplier. You will see later that survey statisticians like to view the center of the sandwich as a variance estimator for totals. They use a multiplier of \( n/(n-1) \), just as \( 1/(n-1) \) is used for the variance estimator of a mean. However, for survey data, \( n \) is no longer the total number of observations but is the number of clusters in a stratum. See Methods and formulas at the end of this entry.

Linear regression is, however, special. Assuming homoskedasticity and normality, you can derive the expectation of \( \hat{e}_j^2 \) for finite \( n \). This is discussed in [R] regress. Under the assumptions of homoskedasticity and normality, \( n/(n-k) \) is a better multiplier than \( n/(n-1) \).

If you specify the minus(#) option, _robust will use \( n/(n-#) \) as the multiplier. regress, vce(robust) also gives two other options for the multiplier: hc2 and hc3. Because these multipliers are special to linear regression, _robust does not compute them.

### Example 1

Before we show how _robust is used, let’s compute the robust variance estimator “by hand” for linear regression for the case in which observations are independent (that is, no clusters).

We need to compute \( D = (X'X)^{-1} \) and the residuals \( \hat{e}_j \). regress with the mse1 option will allow us to compute both easily; see [R] regress.

```
use http://www.stata-press.com/data/r15/_robust
(1978 Automobile Data -- modified)
regress mpg weight gear_ratio foreign, mse1
(output omitted)
matrix D = e(V)
predict double e, residual
```

We can write the center of the sandwich as

\[ M = \sum_{j=1}^{n} \hat{e}_j^2 x'_j x_j = X'WX \]

where \( W \) is a diagonal matrix with \( \hat{e}_j^2 \) on the diagonal. matrix accum with iweights can be used to calculate this (see [P] matrix accum):

```
matrix accum M = weight gear_ratio foreign [iweight=e^2]
(obs=813.7814109)
```
We now assemble the sandwich. To match `regress, vce(robust)`, we use a multiplier of $n/(n-k)$.

\[
\begin{align*}
\text{matrix } & V = 74/70 \times D\cdot M\cdot D \\
\text{matrix list } & V \\
\text{symmetric } & V[4,4] \\
\text{weight} & \quad \text{gear\_ratio} \quad \text{foreign} \quad \_\text{cons} \\
\text{weight} & \quad 3.788\times 10^{-7} \\
\text{gear\_ratio} & \quad 0.00039798 \quad 1.9711317 \\
\text{foreign} & \quad 0.00008463 \quad -0.55488334 \quad 1.4266939 \\
\_\text{cons} & \quad -0.00236851 \quad -6.9153285 \quad 1.2149035 \quad 27.536291
\end{align*}
\]

The result is the same as that from `regress, vce(robust)`:

\[
\begin{align*}
. & \text{regress mpg weight gear\_ratio foreign, vce(robust)} \\
& \text{(output omitted)} \\
. & \text{matrix Vreg = e(V)} \\
. & \text{matrix list Vreg} \\
\text{symmetric } & Vreg[4,4] \\
\text{weight} & \quad \text{gear\_ratio} \quad \text{foreign} \quad \_\text{cons} \\
\text{weight} & \quad 3.788\times 10^{-7} \\
\text{gear\_ratio} & \quad 0.00039798 \quad 1.9711317 \\
\text{foreign} & \quad 0.00008463 \quad -0.55488334 \quad 1.4266939 \\
\_\text{cons} & \quad -0.00236851 \quad -6.9153285 \quad 1.2149035 \quad 27.536291
\end{align*}
\]

If we use `_robust`, the initial steps are the same. We still need $D$, the “bread” of the sandwich, and the residuals. The residuals $e$ are the varlist for `_robust`. $D$ is overwritten and contains the robust variance estimate.

\[
. \text{drop e} \\
. \text{regress mpg weight gear\_ratio foreign, mse1} \\
& \text{(output omitted)} \\
. \text{matrix D = e(V)} \\
. \text{predict double e, residual} \\
. \_\text{robust e, v(D) minus(4)} \\
. \text{matrix list D} \\
\text{symmetric } & D[4,4] \\
\text{weight} & \quad \text{gear\_ratio} \quad \text{foreign} \quad \_\text{cons} \\
\text{weight} & \quad 3.788\times 10^{-7} \\
\text{gear\_ratio} & \quad 0.00039798 \quad 1.9711317 \\
\text{foreign} & \quad 0.00008463 \quad -0.55488334 \quad 1.4266939 \\
\_\text{cons} & \quad -0.00236851 \quad -6.9153285 \quad 1.2149035 \quad 27.536291
\]

Rather than specifying the `variance()` option, we can use `ereturn post` to post $D$ and the point estimates. `_robust` alters the post, substituting the robust variance estimates.

\[
. \text{drop e} \\
. \text{regress mpg weight gear\_ratio foreign, mse1} \\
& \text{(output omitted)} \\
. \text{matrix D = e(V)} \\
. \text{matrix b = e(b)} \\
. \text{local n = e(N)} \\
. \text{local k = colsof(D)} \\
. \text{local dof = `n' - `k'} \\
. \text{predict double e, residual} \\
. \text{ereturn post b D, dof(`dof')} \\
. \_\text{robust e, minus(`k')}
. ereturn display

|        | Robust Coef. | Std. Err. | t | P>|t| | [95% Conf. Interval] |
|--------|--------------|-----------|---|------|---------------------|
| weight | -.006139     | .0006155  | -9.97 | 0.000 | -0.0073666 to -.0049115 |
| gear_ratio | 1.457113     | 1.40397   | 1.04 | 0.303 | -1.343016 to 4.257243 |
| foreign | -2.221682    | 1.194443  | -1.86 | 0.067 | -4.603923 to .1605598 |
| _cons  | 36.10135     | 5.247503  | 6.88 | 0.000 | 25.63554 to 46.56717 |

Again what we did matches `regress, vce(robust)`:

. regress mpg weight gear_ratio foreign, vce(robust)

Technical note

Note the simple ways in which `_robust` was called. When we used the `variance()` option, we called it by typing

. `_robust e, v(D) minus(4)`

As we described, `_robust` computed

\[
\hat{V}(\hat{\beta}) = D \left( \frac{n}{n-k} \sum_{j=1}^{n} \hat{e}_j^2 x'_j x_j \right) D
\]

We passed \(D\) to `_robust` by using the `v(D)` option and specified \(\hat{e}_j\) as the variable `e`. So how did `_robust` know what variables to use for \(x_j\)? It got them from the row and column names of the matrix \(D\). Recall how we generated \(D\) initially:

. `regress mpg weight gear_ratio foreign, mse1`
(output omitted)
. `matrix D = e(V)`
. `matrix list D`

symmetric D[4,4]

<table>

<td>3.3988878</td>
</tr>
</tbody>
</table>
Stata’s estimation commands and the `ml` commands produce matrices with appropriately labeled rows and columns. If that is how we generate our \( D \), this will be taken care of automatically. But if we generate \( D \) in another manner, we must be sure to label it appropriately; see [P] matrix rownames.

When \_robust is used after `ereturn post`, it gets the variable names from the row and column names of the posted matrices. So again, the matrices must be labeled appropriately.

Let us make another rather obvious comment. \_robust uses the variables from the row and column names of the \( D \) matrix at the time \_robust is called. It is the programmer’s responsibility to ensure that the data in these variables have not changed and that \_robust selects the appropriate observations for the computation, using an `if` restriction if necessary (for instance, `if e(sample)`).

### Clustered data

#### Example 2

To get robust variance estimates for clustered data or for complex survey data, simply use the `cluster()`, `strata()`, etc., options when you call \_robust.

The first steps are the same as before. For clustered data, the number of degrees of freedom of the \( t \) statistic is the number of clusters minus one (we will discuss this later).

```
. drop e
. quietly regress mpg weight gear_ratio foreign, mse1
. generate byte samp = e(sample)
. matrix D = e(V)
. matrix b = e(b)
. predict double e, residual
. local k = colsof(D)
. tabulate rep78

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>

</tr>
<tr>
<td>Total</td>
<td>69</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>

. local nclust = r(r)
. display `nclust'
5
. local dof = `nclust' - 1
. ereturn post b D, dof(`dof') esample(samp)
. _robust e, minus(`k') cluster(rep78)
```
. ereturn display

(Std. Err. adjusted for 5 clusters in rep78)

|            | Robust Coef. | Std. Err. | t    | P>|t|  | [95% Conf. Interval] |
|------------|--------------|-----------|------|------|---------------------|
| weight     | -.006139     | .0008399  | -7.31| 0.002| -.008471            |
| gear_ratio | 1.457113     | 1.801311  | 0.81 | 0.464| 6.458355            |
| foreign    | -2.221682    | .8144207  | -2.73| 0.053| .0395129            |
| _cons      | 36.10135     | 3.39887   | 10.62| 0.000| 45.53813            |

What you get is, of course, the same as `regress, vce(cluster rep78)`. Wait a minute. It is not the same!

. regress mpg weight gear_ratio foreign, vce(cluster rep78)

Linear regression

Number of obs = 69
F(3, 4) = 78.61
Prob > F = 0.0005
R-squared = 0.6631
Root MSE = 3.4827

(Std. Err. adjusted for 5 clusters in rep78)

|            | Robust Coef. | Std. Err. | t    | P>|t|  | [95% Conf. Interval] |
|------------|--------------|-----------|------|------|---------------------|
| weight     | -.005893     | .0008214  | -7.17| 0.002| -.0081735           |
| gear_ratio | 1.904503     | 2.18322   | 0.87 | 0.432| 7.966093            |
| foreign    | -2.149017    | 1.20489   | -1.78| 0.149| 1.196295            |
| _cons      | 34.09959     | 4.215275  | 8.09 | 0.000| 45.80307            |

Not even the point estimates are the same. This is the classic programmer’s mistake of not using the same sample for the initial `regress, mse1` call as done with `_robust`. The cluster variable `rep78` is missing for 5 observations. `_robust` omitted these observations, but `regress, mse1` did not.

`_robust` is best used only in programs for just this reason. So, you can write a program and use `msample` and `markout` (see `[P] mark`) to determine the sample in advance of running `regress` and `_robust`. 
Running this program produces the same results as `regress, vce(cluster clustvar)`.

```
. myreg mpg weight gear_ratio foreign, cluster(rep78)
(Std. Err. adjusted for 5 clusters in rep78)

<table>
<thead>
<tr>
<th></th>

</tr>
</tbody>
</table>
```
### Survey data

#### Example 3

We will now modify our `myreg` command so that it handles complex survey data. Our new version will allow `pweight` and `iweight`s, stratification, and clustering.

```stata
begin myreg.ado

program myreg, eclass
version 15.0
syntax varlist [if] [in] [pweight iweight] [ , /*
   */ STRata(varname) CLuster(varname) ]
marksample touse, zeroweight
markout `touse' `cluster' `strata', strok
if ""weight""!="" {
   tempvar w
   quietly generate double `w' `exp' if `touse'
   local iwexp [iw=`w']
   if "`weight'" == "pweight" {
      capture assert `w' >= 0 if `touse'
      if c(rc) error 402
   }
}
if "`cluster'"!="" {
   local clopt "cluster(`cluster')"
}
if "`strata'"!="" {
   local stopt "strata(`strata')"
}
tempvar e
tempname D b
regress `varlist' `iwexp' if `touse', msel
matrix `D' = e(V)
matrix `b' = e(b)
predict double `e' if `touse', residual
_robust `e' `iwexp' if `touse', V(`D') `clopt' `stopt' zeroweight
local dof = r(N_clust) - r(N_strata)
local depn : word 1 of `varlist'
ereturn post `b' `D', depn(`depn') dof(`dof') esample(`touse')
display
ereturn display
end
```

end myreg.ado
```

Note the following details about our version of `myreg` for survey data:

- We called `_robust` before we posted the matrices with `ereturn post`, whereas in our previous version of `myreg`, we called `ereturn post` and then `_robust`. Here we called `_robust` first so that we could use its `r(N_strata)`, containing the number of strata, and `r(N_clust)`, containing the number of clusters; see Stored results at the end of this entry. We did this so that we could pass the correct degrees of freedom (= number of clusters − number of strata) to `ereturn post`. This works even if the `strata()` and `cluster()` options are not specified: `r(N_strata) = 1` if `strata()` is not specified (there truly is one stratum); and `r(N_clust) = number of observations` if `cluster()` is not specified (each observation is a cluster).

- The call to `_robust` was made with `iweight`s, whether `myreg` was called with `pweight` or `iweight`s. Computationally, `_robust` treats `pweight`s and `iweight`s the same. The only difference is that it puts out an error message if it encounters a negative `pweight`, whereas
negative *i*weights are allowed. As good programmers, we put out the error message early before any time-consuming computations are done.

- We used the `zeroweight` option with the `marksample` command so that zero weights would not be excluded from the sample. We gave the `zeroweight` option with `*robust` so that it, too, would not exclude zero weights.

Observations with zero weights affect results only by their effect (if any) on the counts of the clusters. Setting some weights temporarily to zero will, for example, produce subpopulation estimates. If subpopulation estimates are desired, however, it would be better to implement `*robust`'s `subpop()` option and restrict the call to `regress, mse1` to this subpopulation.

- Stata's `svyset` accepts a `psu` variable rather than having a `cluster()` option. This is only a matter of style. They are synonyms, as far as `*robust` is concerned.

Our program gives the same results as `svy: regress`. For our example, we add a `strata` variable and a `psu` variable to the `auto` dataset.

```stata
. use http://www.stata-press.com/data/r15/auto, clear
   (1978 Automobile Data)
. set seed 1
. generate strata = int(3*runiform()) + 1
. generate psu = int(5*runiform()) + 1
. myreg mpg weight gear_ratio foreign [pw=displ], strata(strata) cluster(psu)
```

| mpg    | Coef. | Std. Err. | t     | P>|t|    | [95% Conf. Interval] |
|--------|-------|-----------|-------|--------|----------------------|
| weight | -.0057248 | .000388 | -14.75 | 0.000 | -.0065702 - .0048794 |

Controlling the header display

Example 4

Let's compare the output for our survey version of `myreg` with the earlier version that handled only clustering. The header for the earlier version was

```
(Std. Err. adjusted for 5 clusters in rep78)
```

The header for the survey version lacked the word “Robust” above “Std. Err.”, and it lacked the banner “(Std. Err. adjusted for # clusters in `varname`)”.

Both of these headers were produced by `ereturn display`, and programmers can control what it produces. The word above “Std. Err.” is controlled by setting `e(vcetype)`. The banner “(Std. Err. adjusted for # clusters in `varname`)” is controlled by setting `e(clustvar)` to the cluster variable name. These can be set using the `ereturn local` command; see `[P] ereturn`.

When `_robust` is called after `ereturn post` (as it was in the earlier version that produced the above header), it automatically sets these macros. To not display the banner, the code should read

```
ereturn post ...
_robust ...
ereturn local clustvar ""
```

We can also change the phrase displayed above “Std. Err.” by resetting `e(vcetype)`. To display nothing there, reset `e(vcetype)` to empty—`ereturn local vcetype ""`

For our survey version of `myreg`, we called `_robust` before calling `ereturn post`. Here `_robust` does not set these macros. Trying to do so would be futile because `ereturn post` clears all previous estimation results, including all `e()` macros, but you can set them yourself after calling `ereturn post`. We make this addition to our survey version of `myreg`:

```
_robust ...
return post ...
ereturn local vcetype "Design-based"
```

The output is

```
. myreg mpg weight gear_ratio foreign [pw=displ], strata(strata) cluster(psu)

```
Maximum likelihood estimators

Maximum likelihood estimators are basically no different from linear regression when it comes to the use of \texttt{robust}. We will first do a little statistics and then give a simple example.

We can write our maximum-likelihood estimation equation as

\[
G(\beta) = \sum_{j=1}^{n} S(\beta; y_j, x_j) = 0
\]

where \(S(\beta; y_j, x_j) = \partial \ln L_j / \partial \beta\) is the score and \(\ln L_j\) is the log likelihood for the \(j\)th observation. Here \(\beta\) represents all the parameters in the model, including any auxiliary parameters. We will discuss how to use \texttt{robust} when there are auxiliary parameters or multiple equations in the next section. But for now, all the theory works out fine for any set of parameters.

Using a first-order Taylor-series expansion (that is, the delta method), we can write the variance of \(G(\beta)\) as

\[
\hat{V}\{G(\beta)\}_{\beta=\hat{\beta}} = \frac{\partial G(\beta)}{\partial \beta} \bigg|_{\beta=\hat{\beta}} \hat{V}(\beta) \frac{\partial G(\beta)}{\partial \beta'} \bigg|_{\beta=\hat{\beta}}
\]

Solving for \(\hat{V}(\beta)\) gives

\[
\hat{V}(\beta) = \left[ \left\{ \frac{\partial G(\beta)}{\partial \beta} \right\}^{-1} \hat{V}\{G(\beta)\} \left\{ \frac{\partial G(\beta)}{\partial \beta'} \right\}^{-1} \right]_{\beta=\hat{\beta}}
\]

but

\[
H = \frac{\partial G(\beta)}{\partial \beta}
\]

is the Hessian (matrix of second derivatives) of the log likelihood. Thus we can write

\[
\hat{V}(\beta) = \mathbf{D} \hat{V}\{G(\beta)\}_{\beta=\hat{\beta}} \mathbf{D}
\]

where \(\mathbf{D} = -H^{-1}\) is the traditional covariance estimate.

Now \(G(\beta)\) is simply a sum, and we can estimate its variance just as we would the sum of any other variable—it is \(n^2\) times the standard estimator of the variance of a mean:

\[
\frac{n}{n-1} \sum_{j=1}^{n} (z_j - \bar{z})^2
\]

But here, the scores \(u_j = S(\hat{\beta}; y_j, x_j)\) are (row) vectors. Their sum, and thus their mean, is zero. So, we have

\[
\hat{V}\{G(\beta)\}_{\beta=\hat{\beta}} = \frac{n}{n-1} \sum_{j=1}^{n} u'_j u_j
\]

Thus our robust variance estimator is

\[
\hat{V}(\beta) = \mathbf{D} \left( \frac{n}{n-1} \sum_{j=1}^{n} u'_j u_j \right) \mathbf{D}
\]
so we see that the robust variance estimator is just the delta method combined with a simple estimator for totals!

The above estimator for the variance of the total (the center of the sandwich) is appropriate only when observations are independent. For clustered data and complex survey data, this estimator is replaced by one appropriate for the independent units of the data. Clusters (or PSUs) are independent, so we can sum the scores within a cluster to create a “superobservation” and then use the standard formula for a total on these independent superobservations. Our robust variance estimator thus becomes

$$\hat{V}(\hat{\beta}) = D \left\{ \frac{n_c}{n_c - 1} \sum_{i=1}^{n_c} \left( \sum_{j \in C_i} u_j \right) ' \left( \sum_{j \in C_i} u_j \right) \right\} D$$

where $C_i$ contains the indices of the observations belonging to the $i$th cluster for $i = 1, 2, \ldots, n_c$, with $n_c$ the total number of clusters.

See [SVY] variance estimation for the variance estimator for a total that is appropriate for complex survey data. Our development here has been heuristic. We have, for instance, purposefully omitted sampling weights from our discussion; see [SVY] variance estimation for a better treatment.

Technical note

It is easy to see where the appropriate degrees of freedom for the robust variance estimator come from: the center of the sandwich is $n^2$ times the standard estimator of the variance for the mean of $n$ observations. A mean divided by its standard error has exactly a Student’s $t$ distribution with $n - 1$ degrees of freedom for normal i.i.d. variables but also has approximately this distribution under many other conditions. Thus a point estimate divided by the square root of its robust variance estimate is approximately distributed as a Student’s $t$ with $n - 1$ degrees of freedom.

More importantly, this also applies to clusters, where each cluster is considered a “superobservation”. Here the degrees of freedom is $n_c - 1$, where $n_c$ is the number of clusters (superobservations). If there are only a few clusters, confidence intervals using $t$ statistics can become quite large. It is just like estimating a mean with only a few observations.

When there are strata, the degrees of freedom is $n_c - L$, where $L$ is the number of strata; see [SVY] variance estimation for details.

Not all of Stata’s maximum likelihood estimators that produce robust variance estimators for clustered data use $t$ statistics. Obviously, this matters only when the number of clusters is small. Users who want to be rigorous in handling clustered data should use the svy prefix, which always uses $t$ statistics and adjusted Wald tests (see [R] test). Programmers who want to impose similar rigor should do likewise.

We have not yet given any details about the functional form of our scores $u_j = \frac{\partial \ln L_j}{\partial \beta}$. The log likelihood $\ln L_j$ is a function of $x_j \hat{\beta}$ (the “index”). Logistic regression, probit regression, and Poisson regression are examples. There are no auxiliary parameters, and there is only one equation.

We can then write $u_j = \hat{s}_j x_j$, where

$$\hat{s}_j = \left. \frac{\partial \ln L_j}{\partial (x_j \beta)} \right|_{\beta = \hat{\beta}}$$
We refer to $s_j$ as the equation-level score. Our formula for the robust estimator when observations are independent becomes

$$
\hat{V}(\hat{\beta}) = D \left( \frac{n}{n - 1} \sum_{j=1}^{n} \hat{s}_j^2 x_j' x_j \right) D
$$

This is precisely the formula that we used for linear regression, with $\hat{e}_j$ replaced by $\hat{s}_j$ and $k = 1$ in the multiplier.

Before we discuss auxiliary parameters, let’s show how to implement _robust for single-equation models.

**Example 5**

The robust variance implementation for single-equation maximum-likelihood estimators with no auxiliary parameters is almost the same as it is for linear regression. The only differences are that $D$ is now the traditional covariance matrix (the negative of the inverse of the matrix of second derivatives) and that the variable passed to _robust is the equation-level score $\hat{s}_j$ rather than the residuals $\hat{e}_j$.

Let’s alter our last myreg program for survey data to make a program that does logistic regression for survey data. We have to change only a few lines of the program.

```
begin mylogit.ado

program mylogit, eclass
    version 15.0
    syntax varlist [if] [in] [pweight] [, /*
    */ STRata(varname) CLuster(varname) ]
    marksample touse, zeroweight
    markout 'touse' 'strata' 'cluster', strok
    if "'weight'"!="" {
        tempvar w
        quietly generate double 'w' 'exp' if 'touse'
        local iwexp "[iw='w']"
        capture assert 'w' >= 0 if 'touse' if c(rc) error 402
    }
    if "'cluster'"!="" {
        local clopt "cluster('cluster')"
    }
    if "'strata'"!="" {
        local stopt "strata('strata')"
    }
    tempvar s
    tempname D b
    quietly {
        logit 'varlist' 'iwexp' if 'touse'
        matrix 'D' = e(V)
        matrix 'b' = e(b)
        predict double 's' if e(sample), score
        _robust 's' 'iwexp' if e(sample), v('D') 'clopt' 'stopt' zeroweight
        local dof = r(N_clust) - r(N_strata)
        local depn : word 1 of 'varlist'
        replace 'touse' = e(sample)
        ereturn post 'b' 'D', depn('depn') dof('dof') esample('touse')
        ereturn local vcetype "Design-based"
    }
    display
ereturn display
end
```
Note the following about our program:

- We use the `score` option of `predict` after `logit` to obtain the equation-level scores. If `predict` does not have a `score` option, then we must generate the equation-level score variable some other way.

- `logit` is a unique command in that it will sometimes drop observations for reasons other than missing values (for example, when success or failure is predicted perfectly), so our ‘`touse`’ variable may not represent the true estimation sample. That is why we used the if `e(sample)` condition with the `predict` and `_robust` commands. Then, to provide `ereturn post` with an appropriate `esample()` option, we set the ‘`touse`’ variable equal to the `e(sample)` from the `logit` command and then use this ‘`touse`’ variable in the `esample()` option.

Our `mylogit` program gives the same results as `svy: logit`:

```stata
.mylogit foreign mpg weight gear_ratio [pw=displ], strata(strata) cluster(psu)
```

Technical note

The theory developed here applies to full-information maximum-likelihood estimators. Conditional likelihoods, such as conditional (fixed-effects) logistic regression (clogit) and Cox regression (stcox), use variants on this theme. The `vce(robust)` option on `stcox` uses a similar, but not identical, formula; see [ST] `stcox` and Lin and Wei (1989) for details.
On the other hand, the theory developed here applies not only to maximum likelihood estimators but also to general estimating equations:

$$G(\beta) = \sum_{j=1}^{n} g(\beta; y_j, x_j) = 0$$

See Binder (1983) for a formal development of the theory.

Programmers: You are responsible for the theory behind your implementation.

---

### Multiple-equation estimators

The theory for auxiliary parameters and multiple-equation models is no different from that described earlier. For independent observations, just as before, the robust variance estimator is

$$\hat{V}(\hat{\beta}) = D \left( \frac{1}{n-1} \sum_{j=1}^{n} u_j'^{\prime} D u_j \right) D$$

where $u_j = \partial \ln L_j / \partial \beta$ is the score (row) vector and $D$ is the traditional covariance estimate (the negative of the inverse of the matrix of second derivatives).

With auxiliary parameters and multiple equations, $\beta$ can be viewed as the vector of all the parameters in the model. Without loss of generality, you can write the log likelihood as

$$\ln L_j = \ln L_j(x_j^{(1)} \beta^{(1)}, x_j^{(2)} \beta^{(2)}, \ldots, x_j^{(p)} \beta^{(p)})$$

An auxiliary parameter is regarded as $x_j^{(i)} \beta^{(i)}$ with $x_j \equiv 1$ and $\beta^{(i)}$ a scalar. The score vector becomes

$$u_j = (s_j^{(1)} x_j^{(1)} s_j^{(2)} x_j^{(2)} \ldots s_j^{(p)} x_j^{(p)})$$

where $s_j^{(i)} = \partial \ln L_j / \partial (x_j \beta^{(i)})$ is the equation-level score for the $i$th equation.

This notation has been introduced so that it is clear how to call _robust. You use

```
. _robust s_j^{(1)} s_j^{(2)} \ldots s_j^{(p)} , options
```

where $s_j^{(1)}$, etc., are variables that contain the equation-level score values. The $D$ matrix that you pass to _robust or post with _ereturn post must be labeled with exactly $p$ equation names.

_robust takes the first equation-level score variable, $s_j^{(1)}$, and matches it to the first equation on the $D$ matrix to determine $x_j^{(1)}$, takes the second equation-level score variable and matches it to the second equation, etc. Some examples will make this perfectly clear.

---

**Example 6**

Here is what a matrix with equation names looks like, ending with a call to _robust

```
. generate cat = rep78 - 3
   (5 missing values generated)
. replace cat = 2 if cat < 0
   (10 real changes made)
. mlogit cat price foreign, base(0)
   (output omitted)
. matrix D = e(V)
```

---

---

```stata
. matrix list D
symmetric D[9,9]

0: 0: 0: 1: 1:
 0: 1: 1:
    o. o. o. o.
 0:o.price 0
0:o.foreign 0 0
0:o._cons 0 0 0
1:price 0 0 0 1.240e-08
1:foreign 0 0 0 -1.401e-06 .59355402
1:_cons 0 0 0 -.00007592 -.13992997
2:price 0 0 0 4.265e-09 -5.366e-07
2:foreign 0 0 0 -1.590e-06 .37202359
2:_cons 0 0 0 -.0000265 -.0343682

1: 2: 2: 2:
 1: 2: 2: 2:
    _cons price foreign _cons
 1:_cons .61347545
2:price -.00002693 1.207e-08
2:foreign -.02774147 -3.184e-06 .56833686
2:_cons .20468675 -.00007108 -.1027108 .54017838
```

where s1, s2, and s3 are the equation-level score variables.

Covariance matrices from models with auxiliary parameters look just like multiple-equation matrices. The second equation consists of the auxiliary parameter only. We again end with a call to `robust`.

```stata
. matrix list D
symmetric D[5,5]

eq1:  eq1:  eq1:  eq1:  sigma:
  eq1:  eq1:  eq1:  eq1:  
    weight gear_ratio foreign _cons _cons
  eq1:weight 5.978e-07
  eq1:gear_ratio .00069222 2.2471526
  eq1:foreign .00011344 -.88159935 1.4426905
  eq1:_cons -.00392566 -8.6029018 1.8864693 37.377729
  sigma:_cons -3.527e-14 -3.915e-10 -1.035e-10 -4.552e-09 .07430437
```

We will now give an example using `ml` and `robust` to produce an estimation command that has `vce(robust)` and `vce(cluster clustvar)` options. You can actually accomplish all of this easily by using `ml` without using the `robust` command because `ml` has `robust` and `cluster()` options. We will pretend that these two options are unavailable to illustrate the use of `robust`.

To keep the example simple, we will do linear regression as a maximum likelihood estimator. Here the log likelihood is

\[
\ln L_j = - \frac{1}{2} \left\{ \left( \frac{y_j - x_j \beta}{\sigma} \right)^2 + \ln(2\pi\sigma^2) \right\}
\]
There is an auxiliary parameter, $\sigma$, and thus we have two equation-level scores:

$$\frac{\partial \ln L_j}{\partial (x_j \beta)} = \frac{y_j - x_j \beta}{\sigma^2}$$

$$\frac{\partial \ln L_j}{\partial \sigma} = \frac{1}{\sigma} \left\{ \left( \frac{y_j - x_j \beta}{\sigma} \right)^2 - 1 \right\}$$

Here are programs to compute this estimator. We have two ado-files: `mymle.ado` and `likereg.ado`. The first ado-file contains two programs, `mymle` and `Scores`. `mymle` is the main program, and `Scores` is a subprogram that computes the equation-level scores after we compute the maximum likelihood solution. Because `Scores` is called only by `mymle`, we can nest it in the `mymle.ado` file; see [U] 17 Ado-files.

```
begin mymle.ado

program mymle, eclass
    version 15.0
    local options "Level(cilevel)"
    if replay() {
        if "'e(cmd)'"!="mymle" {
            error 301
        } syntax [, 'options'
            ml display, level('level')
            exit
        }
        syntax varlist [if] [in] [, /*
            'options' Robust CLuster(varname) * ]
    }

    /* Determine estimation sample. */
    marksample touse
    if "'cluster'"!="" {
        markout 'touse' 'cluster', strok
        local clopt "cluster('cluster')"
    }

    /* Get starting values. */
    tokenize 'varlist'
    local depn "'1'"
    macro shift
    quietly summarize 'depn' if 'touse'
    local cons = r(mean)
    local sigma = r(sd)

    /* Do ml. */
    ml model lf likereg ('depn='*) (sigma:) if 'touse', /*
        */ init(/eq1='cons' /sigma='sigma') max /*
        */ title("MLE linear regression") 'options'
    if "'robust'"!="" | "'cluster'"!="" {
        tempvar s1 s2
        Scores 'depn' 's1' 's2'
        _robust 's1' 's2' if 'touse', 'clopt'
    }
    ereturn local cmd "mymle"
    ml display, level('level')
end
```
program Scores
  version 15.0
  args depn s1 s2
  quietly {
    predict double `s1'
    gen double `s2' = (((`depn' - `s1')/[sigma]_[_cons])^2 - 1) /*
    */ /[sigma]_[_cons]
    replace `s1' = (`depn' - `s1')/([sigma]_[_cons]^2)
  }
end

Our likereg program computes the likelihood. Because it is called by Stata's ml commands, we cannot nest it in the other file.

begin likereg.ado
  program likereg
    version 15.0
    args lf xb s
    qui replace `lf' = -0.5*((($ML_y1 - `xb')/'s')^2 + log(2*_pi*'s'^2))
  end
end likereg.ado

Note the following:

• Our command _mymle_ will produce robust variance estimates if either the _robust_ or the _cluster()_ option is specified. Otherwise, it will display the traditional estimates.

• We used the _lf_ method with _ml_; see [R] _ml_. We could have used the _d1_ or _d2_ methods. Because we would probably include code to compute the first derivatives analytically for the _vce(robust)_ option, there is no point in using _d0_. (However, we could compute the first derivatives numerically and pass these to _-_robust.)

• Our _Scores_ program uses _predict_ to compute the index $x_j \beta$. Because we had already posted the results using _ml_, _predict_ is available to us. By default, _predict_ computes the index for the first equation.

• Again because we had already posted the results by using _ml_, we can use [sigma]_[_cons] to get the value of $\sigma$; see [U] 13.5 _Accessing coefficients and standard errors_ for the syntax used to access coefficients from multiple-equation models.

• _ml_ calls _ereturn post_, so when we call _-_robust_, it alters the posted covariance matrix, replacing it with the robust covariance matrix. _-_robust_ also sets _e(vcetype)_ and if the _cluster()_ option is specified, it sets _e(clustvar)_ as well.

• We let _ml_ produce _z_ statistics, even when we specified the _cluster()_ option. If the number of clusters is small, it would be better to use _t_ statistics. To do this, we could specify the _dof()_ option on the _ml_ command, but we would have to compute the number of clusters in advance. We could also get the number of clusters from _-_robust_'s _r(N_clust)_ and then repost the matrices by using _ereturn repost_.

If we run our command with the `cluster()` option, we get

```
.mymle mpg weight gear_ratio foreign, cluster(rep78)
```

```
initial:  log likelihood = -219.4845
rescale:   log likelihood = -219.4845

Iteration 0:  log likelihood = -219.4845  (not concave)
Iteration 1:  log likelihood = -207.02829  (not concave)
Iteration 2:  log likelihood = -202.6134
Iteration 3:  log likelihood = -190.01198
Iteration 4:  log likelihood = -181.94871
Iteration 5:  log likelihood = -181.94473
Iteration 6:  log likelihood = -181.94473

MLE linear regression

Number of obs = 69
Wald chi2(3) = 135.82
Log likelihood = -181.94473
Prob > chi2 = 0.0000

(Std. Err. adjusted for 5 clusters in rep78)
Robust

| Coef.  | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|--------|-----------|-------|-------|----------------------|
| _eq1   |           |       |       |                      |
| weight | -0.005893 | 0.000803 | -7.34 | 0.000 | -0.0074669 | -0.0043191 |
| gear_ratio | 1.904503 | 2.134518 | 0.89  | 0.372 | -2.279075 | 6.08808 |
| foreign | -2.149017 | 1.178012 | -1.82 | 0.068 | -4.457879 | 0.1598441 |
| _cons  | 34.09959  | 4.121243 | 8.27  | 0.000 | 26.02211 | 42.17708 |

| sigma  |           |       |       |                      |
| _cons  | 3.380223  | 0.8840543 | 3.82 | 0.000 | 1.647508 | 5.112937 |

These results are similar to the earlier results that we got with our first `myreg` program and `regress`, `vce(cluster rep78)`.

Our likelihood is not globally concave. Linear regression is not globally concave in $\beta$ and $\sigma$. `ml`'s `lf` convergence routine encountered a little trouble in the beginning but had no problem coming to the right solution.

 Stored results

`_robust` stores the following in `r()`:

Scalars

- `r(N)` number of observations
- `r(N_sub)` subpopulation observations
- `r(N_strata)` number of strata
- `r(N_clust)` number of clusters (PSUs)
- `r singleton)` 1 if singleton strata, 0 otherwise
- `r(census)` 1 if census data, 0 otherwise
- `r(df_r)` variance degrees of freedom
- `r(sum_w)` sum of weights
- `r(N_subpop)` number of observations for subpopulation (`subpop()` only)
- `r(sum_wsub)` sum of weights for subpopulation (`subpop()` only)

Macros

- `r(subpop)` `subpop` from `subpop()`
- `r(N_strata)` and `r(N_clust)` are always set. If the `strata()` option is not specified, then `r(N_strata)=1` (there truly is one stratum). If neither the `cluster()` nor the `psu()` option is specified, then `r(N_clust)` equals the number of observations (each observation is a PSU).
When \_robust alters the post of \_ereturn post, it also stores the following in \_e():

\begin{itemize}
  \item \_e(vcetype) Robust
  \item \_e(clustvar) name of cluster (PSU) variable
\end{itemize}

\_e(vcetype) controls the phrase that \_ereturn display displays above “Std. Err.”; \_e(vcetype) can be set to another phrase (or to empty for no phrase). \_e(clustvar) displays the banner “(Std. Err. adjusted for # clusters in varname)”, or it can be set to empty (\_ereturn local clustvar "").

**Methods and formulas**

We give the formulas here for complex survey data from one stage of stratified cluster sampling, as this is the most general case.

Our parameter estimates, \( \hat{\beta} \), are the solution to the estimating equation

\[
G(\beta) = \sum_{h=1}^{L} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} S(\beta; y_{hij}, x_{hij}) = 0
\]

where \((h, i, j)\) index the observations: \( h = 1, \ldots, L \) are the strata; \( i = 1, \ldots, n_h \) are the sampled PSUs (clusters) in stratum \( h \); and \( j = 1, \ldots, m_{hi} \) are the sampled observations in PSU \((h, i)\). The outcome variable is represented by \( y_{hij} \); the explanatory variables are \( x_{hij} \) (a row vector); and \( w_{hij} \) are the weights.

If no weights are specified, \( w_{hij} = 1 \). If the weights are \texttt{aweights}, they are first normalized to sum to the total number of observations in the sample: \( n = \sum_{h=1}^{L} \sum_{i=1}^{n_h} m_{hi} \). If the weights are \texttt{fweights}, the formulas below do not apply; \texttt{fweights} are treated in such a way to give the same results as unweighted observations duplicated the appropriate number of times.

For maximum likelihood estimators, \( S(\beta; y_{hij}, x_{hij}) = \partial \ln L_j / \partial \beta \) is the score vector, where \( \ln L_j \) is the log likelihood. For survey data, this is not a true likelihood, but a “pseudolikelihood”; see \texttt{[SVY] survey}.

Let

\[
D = \left( -\frac{\partial G(\beta)}{\partial \beta} \right)^{-1} \bigg|_{\beta = \hat{\beta}}
\]

For maximum likelihood estimators, \( D \) is the traditional covariance estimate—the negative of the inverse of the Hessian. In the following, the sign of \( D \) does not matter.

The robust covariance estimate calculated by \_robust is

\[
\hat{V}(\beta) = DMD
\]

where \( M \) is computed as follows. Let \( u_{hij} = S(\beta; y_{hij}, x_{hij}) \) be a row vector of scores for the \((h, i, j)\) observation. Let

\[
u_{h\bullet} = \sum_{j=1}^{m_{hi}} w_{hij} u_{hij} \quad \text{and} \quad \overline{u}_{h\bullet} = \frac{1}{n_h} \sum_{i=1}^{n_h} u_{h\bullet}
\]
$M$ is given by

$$M = \frac{n - 1}{n - k} \sum_{h=1}^{L} (1 - f_h) \frac{n_h}{n_h - 1} \sum_{i=1}^{n_h} (u_{hi} - \bar{u}_{h**})' (u_{hi} - \bar{u}_{h**})$$

where $k$ is the value given in the `minus()` option. By default, $k = 1$, and the term $(n - 1)/(n - k)$ vanishes. Stata’s `regress, vce(robust)` and `regress, vce(cluster clustvar)` commands use $k$ equal to the number of explanatory variables in the model, including the constant (Fuller et al. 1986). The `svy` prefix uses $k = 1$.

The specification $k = 0$ is handled differently. If `minus(0)` is specified, $(n - 1)/(n - k)$ and $n_h/(n_h - 1)$ are both replaced by 1.

The factor $(1 - f_h)$ is the finite population correction. If the `fpc()` option is not specified, $f_h = 0$ is used. If `fpc()` is specified and the variable is greater than or equal to $n_h$, it is assumed to contain the values of $N_h$, and $f_h$ is given by $f_h = n_h/N_h$, where $N_h$ is the total number of PSUs in the population belonging to the $h$th stratum. If the `fpc()` variable is less than or equal to 1, it is assumed to contain the values of $f_h$. See [SVY] variance estimation for details.

For the `vsrs()` option and the computation of $\hat{V}_{srswor}$, the `subpop()` option, and the `srssubpop` option, see [SVY] estat and [SVY] subpopulation estimation.

**Description**

scalar define defines the contents of the scalar variable *scalar_name*. The expression may be either a numeric or a string expression. String scalars can hold arbitrarily long strings, even longer than macros, and unlike macros, can also hold binary data. See [U] 12 Data.

scalar dir and scalar list both list the contents of scalars.

scalar drop eliminates scalars from memory.

**Syntax**

Define scalar variable

```
scalar [define] scalar_name = exp
```

List contents of scalars

```
scalar {dir|list} [ _all | scalar_names ]
```

Drop specified scalars from memory

```
scalar drop { _all | scalar_names }
```

**Remarks and examples**

Stata scalar variables are different from variables in the dataset. Variables in the dataset are columns of observations in your data. Stata scalars are named entities that store single numbers or strings, which may include missing values. For instance,

```
. scalar a = 2
. display a + 2
  4
. scalar b = a + 3
. display b
  5
. scalar root2 = sqrt(2)
. display %18.0g root2
  1.414213562373095
. scalar im = sqrt(-1)
. display im
. scalar s = "hello"
. display s
hello
```
Scalar list can be used to display the contents of macros (as can display for reasons that will be explained below), and scalar drop can be used to eliminate scalars from memory:

```
. scalar list
  s = hello
  im = 
  root2 = 1.4142136
  b = 5
  a = 2

. scalar list a b
  a = 2
  b = 5

. scalar drop a b

. scalar list
  s = hello
  im = 
  root2 = 1.4142136

. scalar drop _all

. scalar list
```

Although scalars can be used interactively, their real use is in programs. Stata has macros and scalars, and deciding when to use which can be confusing.

**Example 1**

Let’s examine a problem where either macros or numeric scalars could be used in the solution. There will be occasions in your programs where you need something that we will describe as a mathematical scalar—one number. For instance, let’s assume that you are writing a program and need the mean of some variable for use in a subsequent calculation. You can obtain the mean after `summarize` from `r(mean)` (see *Stored results* in [*R*]: `summarize`), but you must obtain it immediately because the numbers stored in `r()` are reset almost every time you give a statistical command.

Let’s complicate the problem: to make some calculation, you need to calculate the difference in the means of two variables, which we will call `var1` and `var2`. One solution to your problem is to use macros:

```
summarize var1, meanonly
local mean1 = r(mean)
summarize var2, meanonly
local mean2 = r(mean)
local diff = `mean1' - `mean2'
```

Subsequently, you use ‘diff’ in your calculation. Let’s understand how this works. You `summarize var1, meanonly`; including the `meanonly` option suppresses the output from the `summarize` command and the calculation of the variance. You then store the contents of `r(mean)`—the just-calculated mean—in the local macro `mean1`. You then `summarize var2`, again suppressing the output, and save that just-stored result in the local macro `mean2`. Finally, you create another local macro called `diff`, which contains the difference. In making this calculation, you must put the `mean1` and `mean2` local macro names in single quotes because you want the contents of the macros. If the mean of `var1` is 3 and the mean of `var2` is 2, you want the numbers 3 and 2 substituted into the formula for `diff` to produce 1. If you omitted the single quotes, Stata would think that you are referring to the difference—not of the contents of macros named `mean1` and `mean2`—but of two variables named `mean1` and `mean2`. Those variables probably do not exist, so Stata would then produce an error message. In any case, you put the names in the single quotes.
Now let's consider the solution using Stata scalars:

```
summarize var1, meanonly
scalar m1 = r(mean)
summarize var2, meanonly
scalar m2 = r(mean)
scalar df = m1 - m2
```

The program fragments are similar, although this time we did not put the names of the scalars used in calculating the difference—which we called `df` this time—in single quotes. Stata scalars are allowed only in expressions—they are a kind of variable—and Stata knows that you want the contents of those variables.

So, which solution is better? There is certainly nothing to recommend one over the other in terms of program length—both programs have the same number of lines and, in fact, there is a one-to-one correspondence between what each line does. Nevertheless, the scalar-based solution is better, and here is why:

Macros are printable representations of things. When we said `local mean1 = r(mean)`, Stata took the contents of `r(mean)`, converted them into a printable form from its internal (and highly accurate) binary representation, and stored that string of characters in the macro `mean1`. When we created `mean2`, Stata did the same thing again. Then when we said `local diff = 'mean1' - 'mean2'`, Stata first substituted the contents of the macros `mean1` and `mean2`—which are really strings—into the command. If the means of the two variables are 3 and 2, the printable string representations stored in `mean1` and `mean2` are “3” and “2”. After substitution, Stata processed the command `local diff = 3 - 2`, converting the 3 and 2 back into internal binary representation to take the difference, producing the number 1, which it then converted into the printable representation “1”, which it finally stored in the macro `diff`.

All of this conversion from binary to printable representation and back again is a lot of work for Stata. Moreover, although there are no accuracy issues with numbers like 3 and 2, if the first number had been $3.6710823989 \times 10^{-8}$, there would have been. When converting to printable form, Stata produces representations containing up to 17 digits and, if necessary, uses scientific notation. The first number would have become $3.6710823989e-08$, and the last digit would have been lost. In computer scientific notation, 17 printable positions provides you with at least 13 significant digits. This is a lot, but not as many as Stata carries internally.

Now let’s trace the execution of the solution by using scalars. `scalar m1 = r(mean)` quickly copied the binary representation stored in `r(mean)` into the scalar `m1`. Similarly, executing `scalar m2 = r(mean)` did the same thing, although it saved it in `m2`. Finally, `scalar df = m1 - m2` took the two binary representations, subtracted them, and copied the result to the scalar `df`. This produces a more accurate result.

### Naming scalars

Scalars can have the same names as variables in the data and Stata will not become confused. You, however, may. Consider the following Stata command:

```
. generate newvar = alpha*beta
```

What does it mean? It certainly means to create a new data variable named `newvar`, but what will be in `newvar`? There are four possibilities:

- Take the data variable `alpha` and the data variable `beta`, and multiply the corresponding observations together.
- Take the scalar `alpha` and the data variable `beta`, and multiply each observation of `beta` by `alpha`.  

```
• Take the data variable \texttt{alpha} and the scalar \texttt{beta}, and multiply each observation of \texttt{alpha} by \texttt{beta}.

• Take the scalar \texttt{alpha} and the scalar \texttt{beta}, multiply them together, and store the result repeatedly into \texttt{newvar}.

How Stata decides among these four possibilities is the topic of this section.

Stata's first rule is that if there is only one \texttt{alpha} (a data variable or a scalar) and one \texttt{beta} (a data variable or a scalar), Stata selects the one feasible solution and does it. If, however, there is more than one \texttt{alpha} or more than one \texttt{beta}, Stata always selects the data-variable interpretation in preference to the scalar.

Assume that you have a data variable called \texttt{alpha} and a scalar called \texttt{beta}:

\begin{verbatim}
. list
<table>
<thead>
<tr>
<th>alpha</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

. scalar list
   beta = 3

. generate newvar = alpha*beta

. list
<table>
<thead>
<tr>
<th>alpha</th>
<th>newvar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>15</td>
</tr>
</tbody>
</table>
\end{verbatim}

The result was to take the data variable \texttt{alpha} and multiply it by the scalar \texttt{beta}. Now let's start again, but this time, assume that you have a data variable called \texttt{alpha} and both a data variable and a scalar called \texttt{beta}:

\begin{verbatim}
. scalar list
   beta = 3

. list
<table>
<thead>
<tr>
<th>alpha</th>
<th>beta</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
</tr>
</tbody>
</table>

. generate newvar = alpha*beta

. list
<table>
<thead>
<tr>
<th>alpha</th>
<th>beta</th>
<th>newvar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>20</td>
</tr>
</tbody>
</table>
\end{verbatim}
The result is to multiply the data variables, ignoring the scalar beta. In situations like this, you can force Stata to use the scalar by specifying `scalar(beta)` rather than merely `beta`:

```
. generate newvar2 = alpha*scalar(beta)
. list
```

<table>
<thead>
<tr>
<th>alpha</th>
<th>beta</th>
<th>newvar</th>
<th>newvar2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>9</td>
<td>9</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>20</td>
<td>15</td>
</tr>
</tbody>
</table>

The `scalar()` pseudofunction, placed around a name, says that the name is to be interpreted as the name of a scalar, even if a data variable by the same name exists. You can use `scalar()` around all your scalar names if you wish; there need not be a name conflict. Obviously, it will be easiest if you give your data and scalars different names.

**Technical note**

The advice to name scalars and data variables differently may work interactively, but in programming situations, you cannot know whether the name you have chosen for a scalar conflicts with the data variables because the data are typically provided by the user and could have any names whatsoever.

One solution—and not a good one—is to place the `scalar()` pseudofunction around the names of all your scalars when you use them. A much better solution is to obtain the names for your scalars from Stata’s `tempname` facility; see [P] macro. There are other advantages as well. Let’s go back to calculating the sum of the means of variables `var1` and `var2`. Our original draft looked like

```
summarize var1, meanonly
scalar m1 = r(mean)
summarize var2, meanonly
scalar m2 = r(mean)
scalar df = m1 - m2
```

A well-written draft would look like

```
tempname m1 m2 df
summarize var1, meanonly
scalar `m1' = r(mean)
summarize var2, meanonly
scalar `m2' = r(mean)
scalar `df' = `m1' - `m2'
```

We first declared the names of our temporary scalars. Actually, `tempname` creates three new local macros named `m1`, `m2`, and `df`, and places in those macros names that Stata makes up, names that are guaranteed to be different from the data. (`m1`, for your information, probably contains something like `__000001`.) When we use the temporary names, we put single quotes around them—`m1` is not the name we want; we want the name that is stored in the local macro named `m1`.

That is, if we type

```
scalar m1 = r(mean)
```

then we create a scalar named `m1`. After `tempname m1 m2 df`, if we type

```
scalar `m1' = r(mean)
```

then we create a scalar named with whatever name happens to be stored in `m1`. It is Stata’s responsibility to make sure that name is valid and unique, and Stata did that when we issued the `tempname` command. As programmers, we never need to know what is really stored in the macro `m1`; all we need to do is put single quotes around the name whenever we use it.
There is a second advantage to naming scalars with names obtained from `tempname`. Stata knows that they are temporary—when our program concludes, all temporary scalars will be automatically dropped from memory. And, if our program calls another program, that program will not accidentally use one of our scalars, even if the programmer happened to use the same name. Consider

```stata
program myprog
  (lines omitted)
  tempname m1
  scalar `m1' = something
  mysub
  (lines omitted)
end

program mysub
  (lines omitted)
  tempname m1
  scalar `m1' = something else
  (lines omitted)
end
```

Both `myprog` and `mysub` refer to a scalar, `m1`; `myprog` defines `m1` and then calls `mysub`, and `mysub` then defines `m1` differently. When `myprog` regains control, however, `m1` is just as it was before `myprog` called `mysub`!

It is unchanged because the scalar is not named `m1`: it is named something returned by `tempname`—a guaranteed unique name—and that name is stored in the local macro `m1`. When `mysub` is executed, Stata safely hides all local macros, so the local macro `m1` in `mysub` has no relation to the local macro `m1` in `myprog`. `mysub` now puts a temporary name in its local macro `m1`—a different name because `tempname` always returns unique names—and `mysub` now uses that different name. When `mysub` completes, Stata discards the temporary scalars and macros and restores the definitions of the old temporary macros, and `myprog` is off and running again.

Even if `mysub` had been poorly written in the sense of not obtaining its temporary names from `tempname`, `myprog` would have no difficulty. The use of `tempname` by `myprog` is sufficient to guarantee that no other program can harm it. For instance, pretend `mysub` looked like

```stata
program mysub
  (lines omitted)
  scalar m1 = something else
  (lines omitted)
end
```

`mysub` is now directly using a scalar named `m1`. That will not interfere with `myprog`, however, because `myprog` has no scalar named `m1`. Its scalar is named `m1`, a name obtained from `tempname`.

- Technical note

One result of the above is that scalars are not automatically shared between programs. The scalar `m1` in `myprog` is different from either of the scalars `m1` or `m1` in `mysub`. What if `mysub` needs `myprog`’s `m1`?

One solution is not to use `tempname`: you could write `myprog` to use the scalar `m1` and `mysub` to use the scalar `m1`. Both will be accessing the same scalar. This, however, is not recommended.
A better solution is to pass ‘m1’ as an argument. For instance,

```stata
program myprog
    tempname m1
    scalar ‘m1’ = something
    mysub ‘m1’
end

program mysub
    args m1
    commands using ‘m1’
end
```

We passed the name of the scalar given to us by `tempname`—‘m1’—as the first argument to `mysub`. `mysub` picked up its first argument and stored that in its own local macro by the same name—m1. Actually, `mysub` could have stored the name in any macro name of its choosing; the line reading `args m1` could read `args m2`, as long as we changed the rest of `mysub` to use the name ‘m2’ wherever it uses the name ‘m1’.

[P] macro — Macro definition and manipulation
[P] matrix — Introduction to matrix commands
[U] 18.3 Macros
[U] 18.7.2 Temporary scalars and matrices
serset — Create and manipulate sersets

Description

serset creates and manipulates sersets.

file sersetwrite writes and file sersetread reads sersets into files.

The extended macro function :serset reports information about the current serset.

varlist may contain strL variables or str# variables. If it does, only the first 244 bytes of each value will be stored in the serset.

Syntax

Create new serset from data in memory

```
serset create varlist [if] [in] [, omitanymiss omitallmiss omitdupmiss omitnothing sort(varlist)]
```

Create serset of cross medians

```
serset create_xmedians svn_y svn_x [svn_w] [, bands(#) xmin(#) xmax(#) logx logy]
```

Create serset of interpolated points from cubic spline interpolation

```
serset create_cspline svn_y svn_x [, n(#)]
```

Make previously created serset the current serset

```
serset [set] #s
```

Change order of observations in current serset

```
serset sort [svn [svn [...]]]
```

Return summary statistics about current serset

```
serset summarize svn [, detail]
```

Return in r() information about current serset

```
serset
```
Load serset into memory

```
serset use [, clear]
```

Change ID of current serset

```
serset reset_id #_
```

Eliminate specified sersets from memory

```
serset drop [numlist | _all]
```

Eliminate all sersets from memory

```
serset clear
```

Describe existing sersets

```
serset dir
```

The `file` command (see `[P] file`) is also extended to allow

Write serset into file

```
file sersetwrite handle
```

Read serset from file

```
file sersetread handle
```

The following extended macro functions are also available:

<table>
<thead>
<tr>
<th>Extended function</th>
<th>Returns from the current serset</th>
</tr>
</thead>
<tbody>
<tr>
<td>: serset id</td>
<td>ID</td>
</tr>
<tr>
<td>: serset k</td>
<td>number of variables</td>
</tr>
<tr>
<td>: serset N</td>
<td>number of observations</td>
</tr>
<tr>
<td>: serset varnum svn</td>
<td><code>svnnum</code> of <code>svn</code></td>
</tr>
<tr>
<td>: serset type svn</td>
<td><code>svn</code> storage type of <code>svn</code></td>
</tr>
<tr>
<td>: serset format svn</td>
<td><code>svn</code> display format of <code>svn</code></td>
</tr>
<tr>
<td>: serset varnames</td>
<td>list of <code>svns</code></td>
</tr>
<tr>
<td>: serset min svn</td>
<td>minimum of <code>svn</code></td>
</tr>
<tr>
<td>: serset max svn</td>
<td>maximum of <code>svn</code></td>
</tr>
</tbody>
</table>

Extended macro functions have the syntax

```
local macname : ...
```

The current serset is the most recently created or the most recently set by the `serset set` command.
In the above syntax diagrams,

\[ #_s \text{ refers to a serset number, } 0 \leq #_s \leq 1,999. \]

\textit{varlist} refers to the usual Stata \textit{varlist}, that is, a list of variables that appear in the current dataset, not the current serset.

\textit{svn} refers to a variable in a serset. The variable may be referred to by either its name (for example, mpg or 1.gnp) or its number (for example, 1 or 5); which is used makes no difference.

\textit{svnum} refers to a variable number in a serset.

**Options**

Options are presented under the following headings:

- Options for serset create
- Options for serset create\_xmedians
- Option for serset create\_cspline
- Option for serset summarize
- Option for serset use

**Options for serset create**

- \textit{omitanymiss}, \textit{omitallmiss}, \textit{omitdupmiss}, and \textit{omitnothing} specify how observations with missing values are to be treated.

- \textit{omitanymiss} is the default. Observations in which any of the numeric variables contain missing are omitted from the serset being created.

- \textit{omitallmiss} specifies that only observations in which all the numeric variables contain missing be omitted.

- \textit{omitdupmiss} specifies that only duplicate observations in which all the numeric variables contain missing be omitted. Observations omitted will be a function of the sort order of the original data.

- \textit{omitnothing} specifies that no observations be omitted (other than those excluded by \textit{if} \textit{exp} and in \textit{range}).

- \textit{sort(\textit{varlist})} specifies that the serset being created is to be sorted by the specified variables. The result is no different from, after serset creation, using the \textit{serset sort} command, but total execution time is a little faster. The sort order of the data in memory is unaffected by this option.

**Options for serset create\_xmedians**

- \textit{bands(\#)} specifies the number of divisions along the \textit{x} scale in which cross medians are to be calculated; the default is \textit{bands(200)}. \textit{bands()} may be specified to be between 3 and 200.

Let \( m \) and \( M \) specify the minimum and maximum value of \textit{x}. If the scale is divided into \( n \) bands (that is, \textit{bands(n)} is specified), the first band is \( m \) to \( m + (M - m)/n \), the second \( m + (M - m)/n \) to \( m + 2 * (M - m)/n \), ..., and the \( n \)th \( m + (n - 1) * (M - m)/n \) to \( m + n * (M - m)/n = m + M - m = M \).
\texttt{xmin(\#)} and \texttt{xmax(\#)} specify the minimum and maximum values of the \textit{x} variable to be used in the bands calculation—\textit{m} and \textit{M} in the formulas above. The actual minimum and maximum are used if these options are not specified. Also, if \texttt{xmin()} is specified with a number that is greater than the actual minimum, the actual minimum is used, and if \texttt{xmax()} is specified with a number that is less than the actual maximum, the actual maximum is used.

\texttt{logx} and \texttt{logy} specify that cross medians be created using a “log” scale. The exponential of the median of the log of the values is calculated in each band.

**Option for serset create\_cspline**

\texttt{n(\#)} specifies the number of points to be evaluated between each pair of \textit{x} values, which are treated as the knots. The default is \texttt{n(5)}, and \texttt{n()} may be between 1 and 300.

**Option for serset summarize**

\texttt{detail} specifies additional statistics, including skewness, kurtosis, the four smallest and four largest values, and various percentiles. This option is identical to the \texttt{detail} option of \texttt{summarize}; see \texttt{[R] summarize}.

**Option for serset use**

\texttt{clear} permits the serset to be loaded, even if there is a dataset already in memory and even if that dataset has changed since it was last saved.

**Remarks and examples**

Remarks are presented under the following headings:

- \textit{Introduction}
- \texttt{serset create}
- \texttt{serset create\_xmedians}
- \texttt{serset create\_cspline}
- \texttt{serset set}
- \texttt{serset sort}
- \texttt{serset summarize}
- \texttt{serset}
- \texttt{serset use}
- \texttt{serset reset\_id}
- \texttt{serset drop}
- \texttt{serset clear}
- \texttt{serset dir}
- \texttt{file sersetwrite and file sersetread}

**Introduction**

Sersets are used in implementing Stata’s graphics capabilities. When you make a graph, the data for the graph are extracted into a serset and then, at the lowest levels of Stata’s graphics implementation, are graphed from there.

Sersets are like datasets: they contain observations on one or more variables. Each serset is assigned a number, and in your program, you use that number when referring to a serset. Thus multiple sersets can reside simultaneously in memory. (Sersets are, in fact, stored in a combination of memory and temporary disk files, so accessing their contents is slower than accessing the data in memory. Sersets, however, are fast enough to keep up with graphics operations.)
**serset create**

*serset create* creates a new serset from the data in memory. For instance,

```
. serset create mpg weight
```

creates a new serset containing variables *mpg* and *weight*. When using the serset later, you can refer to these variables by their names, *mpg* and *weight*, or by their numbers, 1 and 2.

*serset create* also returns the following in *r()*:

- `r(N)` the number of observations placed into the serset
- `r(k)` the number of variables placed into the serset
- `r(id)` the number assigned to the serset

`r(N)` and `r(k)` are just for your information; by far the most important returned result is `r(id)`. You will need to use this number in subsequent commands to refer to this serset.

*serset create* also sets the current serset to the one just created. Commands that use sersets always use the current serset. If, in later commands, the current serset is not the one desired, you can set the desired one by using *serset set*, described below.

**serset create_xmedians**

*serset create_xmedians* creates a new serset based on the currently set serset. The basic syntax is

```
serset create_xmedians svn y svn x [svn w] [, ...]
```

The new serset will contain cross medians. Put that aside. In the *serset create_xmedians* command, you specify two or three variables to be recorded in the current serset. The result is to create a new serset containing two variables (*svn y* and *svn x*) and a different number of observations. As with *serset create*, the result will also be to store the following in *r()*:

- `r(id)` the number assigned to the serset
- `r(k)` the number of variables in the serset
- `r(N)` the number of observations in the serset

The newly created serset will become the current serset.

In actual use, you might code

```
serset create 'yvar' 'xvar' 'zvar'
local base = r(id)
...
serset set 'base'
serset create_xmedians 'yvar' 'xvar'
local cross = r(id)
...
```

*serset create_xmedians* obtains data from the original serset and calculates the median values of *svn y* and the median values of *svn x* for bands of *svn x* values. The result is a new dataset of *n* observations (one for each band) containing median *y* and median *x* values, where the variables have the same name as the original variables. These results are stored in the newly created serset. If a third variable is specified, *svn w*, the medians are calculated with weights.
serset create_cspline

serset create_cspline works in the same way as serset create_xmedians: it takes one serset and creates another serset from it, leaving the first unchanged. Thus, as with all serset creation commands, returned in \( r() \) is

\[
\begin{align*}
  r(id) & \text{ the number assigned to the serset} \\
  r(k) & \text{ the number of variables in the serset} \\
  r(N) & \text{ the number of observations in the serset}
\end{align*}
\]

and the newly created serset will become the current serset.

serset create_cspline performs cubic spline interpolation, and here the new serset will contain the interpolated points. The original serset should contain the knots through which the cubic spline is to pass. serset create_cspline also has the \( n(#) \) option, which specifies how many points are to be interpolated, so the resulting dataset will have \( N + (N - 1) \times n() \) observations, where \( N \) is the number of observations in the original dataset. A typical use of serset create_cspline would be

\[
\begin{align*}
  \text{serset create 'yvar' 'xvar'} \\
  \text{local base = r(id)} \\
  \ldots \\
  \text{serset set 'base'} \\
  \text{serset create_xmedians 'yvar' 'xvar'} \\
  \text{local cross = r(id)} \\
  \ldots \\
  \text{serset set 'cross'} \\
  \text{serset create_cspline 'yvar' 'xvar'} \\
  \ldots
\end{align*}
\]

Here the spline is placed not through the original data but through cross medians of the data.

serset set

serset set is used to make a previously created serset the current serset. You may omit the set. Typing

\[
\text{serset 5}
\]

is equivalent to typing

\[
\text{serset set 5}
\]

You would never actually know ahead of time the number of a serset that you needed to code. Instead, when you created the serset, you would have recorded the identity of the serset created, say, in a local macro, by typing

\[
\text{local id = r(id)}
\]

and then later, you would make that serset the current serset by coding

\[
\text{serset set 'id'}
\]

serset sort

serset sort changes the order of the observations of the current serset. For instance,

\[
\begin{align*}
  \text{serset create mpg weight} \\
  \text{local id = r(id)} \\
  \text{serset sort weight mpg}
\end{align*}
\]
would place the observations of the serset in ascending order of variable `weight` and, within equal values of `weight`, in ascending order of variable `mpg`.

If no variables are specified after `serset sort`, `serset sort` does nothing. That is not considered an error.

**serset summarize**

`serset summarize` returns summary statistics about a variable in the current serset. It does not display output or in any way change the current serset.

Returned in `r()` is exactly what the `summarize` command returns in `r()`; see [R] `summarize`.

**serset**

`serset` typed without arguments produces no output but returns in `r()` information about the current serset:

- `r(id)` the number assigned to the current serset
- `r(k)` the number of variables in the current serset
- `r(N)` the number of observations in the current serset

If no serset is in use, `r(id)` is set to −1, and `r(k)` and `r(N)` are left undefined; no error message is produced.

**serset use**

`serset use` loads a serset into memory. That is, it copies the current serset into the current data. The serset is left unchanged.

**serset reset_id**

`serset reset_id` is a rarely used command. Its syntax is

```
`serset reset_id #s`
```

`serset reset_id` changes the ID of the current serset—its number—to the number specified, if that is possible. If not, it produces the error message “series #s in use”; `r(111)`.

Either way, the same serset continues to be the current serset (that is, the number of the current serset changes if the command is successful).

**serset drop**

`serset drop` eliminates (erases) the specified sersets from memory. For instance,

```
`serset drop 5`
```

would eliminate serset 5, and

```
`serset drop 5/9`
```
would eliminate sersets 5–9. Using `serset drop` to drop a serset that does not exist is not an error; it does nothing.

Typing `serset drop _all` would drop all existing sersets.

Be careful not to drop sersets that are not yours: Stata’s graphics system creates and holds onto sersets frequently, and, if you drop one of its sersets that are in use, the graph on the screen will eventually “fall apart”, and Stata will produce error messages (Stata will not crash). The graphics system will itself drop sersets when it is through with them.

The `discard` command also drops all existing sersets. This, however, is safe because `discard` also closes any open graphs.

**serset clear**

`serset clear` is a synonym for `serset drop _all`.

**serset dir**

`serset dir` displays a description of all existing sersets.

**file sersetwrite and file sersetread**

`file sersetwrite` and `file sersetread` are extensions to the `file` command; see [P] `file`. These extensions write and read sersets into files. The files may be opened text or binary, but, either way, what is written into the file will be in a binary format.

`file sersetwrite` writes the current serset. A code fragment might read

```plaintext
serset create ...
local base = r(id)
...
tempname hdl
file open 'hdl' using "'filename'", write ...
...
serset set 'base'
file sersetwrite 'hdl'
...
file close 'hdl'
```

`file sersetread` reads a serset from a file, creating a new serset in memory. `file sersetread` returns in `r(id)` the serset ID of the newly created serset. A code fragment might read

```plaintext
tempname hdl
file open 'hdl' using "'filename'", read ...
...
file sersetread 'hdl'
local new = r(id)
...
file close 'hdl'
```

See [P] `file` for more information on the `file` command.
Stored results

`serset create`, `serset create_xmedians`, `serset create_cspline`, `serset set`, and `serset store` the following in `r()`:

- Scalars
  - `r(id)` the serset ID
  - `r(k)` the number of variables in the serset
  - `r(N)` the number of observations in the serset

`serset summarize` returns in `r()` the same results as returned by the `summarize` command.

`serset use` returns in macro `r(varnames)` the names of the variables in the newly created dataset.

`file sersetread` returns in scalar `r(id)` the serset ID, which is the identification number assigned to the serset.

[P] class — Class programming

[P] file — Read and write text and binary files
set locale_functions — Specify default locale for functions

Description

set locale_functions sets the locale to be used by functions that take locale as an optional argument: ustrupper(), ustrlower(), ustrtitle(), ustrword(), ustrwordcount(), ustrcomp(), and ustrsortkey() and their Mata equivalents. When the argument is not specified, the locale_functions setting is used. If locale_functions is not set, the default ICU locale is used.

For example, if your operating system is Microsoft Windows English version, the system locale may be "en". If you chose the specific country to be the United States during installation of your OS, then the system locale is most likely "en_US". If locale_functions is not set or is set to default, then calling ustrupper("istanbul") is equivalent to calling ustrupper("istanbul", "en_US"), which returns ISTANBUL. However, if locale_functions is set to "tr" for Turkish, then calling ustrupper("istanbul") is equivalent to calling ustrupper("istanbul", "tr"), which returns İSTANBUL. For further discussion of locales, see [U] 12.4.2.4 Locales in Unicode.

Note that although ICU does not validate locales, Stata validates the language subtag of the locale_functions setting. It must be a valid ISO-639-2 language code. See the ISO-639-2 list at http://www.loc.gov/standards/iso639-2/.

The current locale_functions setting is stored in c(locale_functions). c(locale_functions) is reset to its original value when a program or do-file exits.

Syntax

Use the system locale for Unicode functions

    set locale_functions default [, permanently]

Specify a locale for Unicode functions

    set locale_functions locale [, permanently]

Option

permanently specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

Also see

    [P] creturn — Return c-class values
    [R] query — Display system parameters
    [R] set — Overview of system parameters
set locale_ui — Specify a localization package for the user interface

Description

set locale_ui sets the locale that Stata uses for the user interface (UI). If a localization package can be matched to the specified locale, the language contained in that package will be used to display various UI elements (menus, dialogs, message boxes, etc.). The setting takes effect the next time Stata starts.

The default language for Stata’s UI elements is English. Currently, additional localization packages exist for Japanese, Spanish, and Swedish.

For example, the command set locale_ui ja, where ja is the language code for Japanese, causes Stata to display menus and various other UI text in Japanese. If a localization package for Japanese cannot be found, then the UI text will continue to be displayed using the English defaults.

For further discussion of locales, see [U] 12.4.2.4 Locales in Unicode.

The current UI setting is stored in c(locale_ui).

Syntax

Use the system locale for user interface localization

    set locale_ui default

Specify a locale for user interface localization

    set locale_ui locale

[R] set — Overview of system parameters
signestimationsample — Determine whether the estimation sample has changed

Description

signestimationsample and checkestimationsample are easy-to-use interfaces into datasignature for use with estimation commands; see [D] datasignature.

signestimationsample obtains a data signature for the estimation sample and stores it in \( e() \).

checkestimationsample obtains a data signature and compares it with that stored by signestimationsample and, if they are different, reports “data have changed since estimation”; \( r(459) \).

If you just want to know whether any of the data in memory have changed since they were last saved, see [D] describe. Examine stored result \( r(changed) \) after describe; it will be 0 if the data have not changed and 1 otherwise.

Syntax

signestimationsample varlist

checkestimationsample

Remarks and examples

Remarks are presented under the following headings:

- Using signestimationsample and checkestimationsample
- Signing
- Checking
- Handling of weights
- Do not sign unnecessarily

Using signestimationsample and checkestimationsample

Estimators often come as a suite of commands: the estimation command itself (say, myest) and postestimation commands such as predict, estat, or even myest_stats. The calculations made by the postestimation commands are sometimes appropriate for use with any set of data values—not just the data used for estimation—and sometimes not. For example, predicted values can be calculated with any set of explanatory variables, whereas scores are valid only if calculated using the original data.

Postestimation calculations that are valid only when made using the estimation sample are the exception, but when they arise, signestimationsample and checkestimationsample provide the solution. The process is as follows:

1. At the time of estimation, sign the estimation sample (store the data’s signature in \( e() \)).
2. At the time of use, obtain the signature of the data in memory and compare it with the original stored previously.
Signing

To sign the estimation sample, include in your estimation command the following line after `e(sample)` is set (that is, after `ereturn post`):

```
. signestimationsample 'varlist'
```

`varlist` should contain all variables used in estimation, string and numeric, used directly or indirectly, so you may in fact code

```
. signestimationsample 'lhsvar' 'rhsvars' 'clustervar'
```
or something similar. If you are implementing a time-series estimator, do not forget to include the time variable:

```
. quietly tsset
. signestimationsample 'r(timevar)' 'lhsvar' 'rhsvars' 'othervars'
```

The time variable may be among the `rhsvars`, but it does not matter if time is specified twice.

If you are implementing an `xt` estimator, do not forget to include the panel variable and the optional time variable:

```
. quietly xtset
. signestimationsample 'r(panelvar)' 'r(timevar)' 'lhsvar' 'rhsvars' 'clustervar'
```

In any case, specify all relevant variables and don’t worry about duplicates. `signestimationsample` produces no output, but behind the scenes, it adds two new results to `e()`:

- `e(datasignature)` — the signature formed by the variables specified in the observations for which `e(sample)` = 1
- `e(datasignaturevars)` — the names of the variables used in forming the signature

Checking

Now that the signature is stored, include the following line in the appropriate place in your postestimation command:

```
. checkestimationsample
```

`checkestimationsample` will compare `e(datasignature)` with a newly obtained signature based on `e(datasignaturevars)` and `e(sample)`. If the data have not changed, the results will match, and `checkestimationsample` will silently return. Otherwise, it will issue the error message “data have changed since estimation”; `r(459)`.

Handling of weights

When you code

```
. signestimationsample 'lhsvar' 'rhsvars' 'clustervar'
```
and

```
. checkestimationsample
```
weights are handled automatically.

That is, when you `signestimationsample`, the command looks for `e(wexp)` and automatically includes any weighting variables in the calculation of the checksum. `checkestimationsample` does the same thing.
Do not sign unnecessarily

signestimationsample and checkestimationsample are excellent solutions for restricting postestimation calculations to the estimation sample. However, most statistics do not need to be so restricted. If none of your postestimation commands need to checkestimationsample, do not bother to signestimationsample.

Calculation of the checksum requires time. It’s not much, but neither is it zero. On a 2.8-GHz computer, calculating the checksum over 100 variables and 50,000 observations requires about a quarter of a second.

Stored results

signestimationsample stores the following in e():

Macros

- e(datasignaturevars) variables used in calculation of checksum
- e(datasignature) the checksum

The format of the stored signature is that produced by datasignature, fast nonames; see [D] datasignature.

**sleep — Pause for a specified time**

<table>
<thead>
<tr>
<th>Description</th>
<th>Syntax</th>
<th>Remarks and examples</th>
</tr>
</thead>
</table>

**Description**

`sleep` tells Stata to pause for `#` ms before continuing with the next command.

**Syntax**

```plaintext
sleep #
```

where `#` is the number of milliseconds (1,000 ms = 1 second).

**Remarks and examples**

Use `sleep` when you want Stata to wait for some amount of time before executing the next command.

```plaintext
    . sleep 10000
```

pauses Stata for 10 seconds.
Description

SMCL, which stands for Stata Markup and Control Language and is pronounced “smickle”, is Stata’s output language. SMCL directives, such as “[it:...]]” in

You can output [it:italics] using SMCL

affect how output appears:

You can output *italics* using SMCL

All Stata output is processed by SMCL: help files, statistical results, and even the output of display (see [P] display) in the programs you write.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- SMCL modes
- Command summary—general syntax
- Help file preprocessor directive for substituting repeated material
- Formatting directives for use in line and paragraph modes
- Link directives for use in line and paragraph modes
- Formatting directives for use in line mode
- Formatting directives for use in paragraph mode
- Directive for entering the as-is mode
- Inserting values from constant and current-value class
- Displaying characters using ASCII and extended ASCII codes
- Advice on using display
- Advice on formatting help files

Introduction

You will use SMCL mainly in the programs you compose and in the help files you write to document them, although you can use it in any context. Everything Stata displays on the screen is processed by SMCL. You can even use some of SMCL’s features to change how text appears in graphs; see [G-4] text.

Your first encounter with SMCL was probably in the Stata session logs created by the log using command. By default, Stata creates logs in SMCL format and gives them the file suffix .smcl. The file suffix does not matter; that the output is in SMCL format does. Files containing SMCL can be redisplayed in their original rendition, and SMCL output can be translated to other formats through the translate command; see [R] translate.

SMCL is mostly just plain text, for instance,

```
   . display "this is SMCL"
   this is SMCL
```

but that text can contain SMCL directives, which are enclosed in braces. Try the following:
. display "{title:this is SMCL, too}"
this is SMCL, too

The “{title:...}” directive told SMCL to output what followed the colon in title format. Exactly
how the title format appears on your screen—or on paper if you print it—will vary, but SMCL will
ensure that it always appears as a recognizable title.

Now try this:

. display "now we will try {help summarize:clicking}"  
now we will try clicking

The word clicking will appear as a link—probably in some shade of blue. Click on the word.
This will bring up Stata's Viewer and show you the help for the summarize command. The SMCL
{help:...} directive is an example of a link. The directive {help summarize:clicking} displayed
the word clicking and arranged things so that when the user clicked on the highlighted word, help
for summarize appeared.

Here is another example of a link:

. display "You can also run Stata commands by {stata summarize mpg:clicking}"  
You can also run Stata commands by clicking

Click on the word, and this time the result will be exactly as if you had typed the command summarize
mpg into Stata. If you have the automobile data loaded, you will see the summary statistics for the
variable mpg.

Simply put, you can use SMCL to make your output look better and to add links.

SMCL modes

SMCL is always in one of three modes:

1. SMCL line mode
2. SMCL paragraph mode
3. As-is mode

Modes 1 and 2 are nearly alike—in these two modes, SMCL directives are understood, and the modes
differ only in how they treat blanks and carriage returns. In paragraph mode—so called because it is
useful for formatting text into paragraphs—SMCL joins one line to the next and splits lines to form
output with lines that are of nearly equal length. In line mode, SMCL shows the line much as you
entered it. For instance, in line mode, the input text

<table>
<thead>
<tr>
<th>Variable name</th>
<th>mean</th>
<th>standard error</th>
</tr>
</thead>
</table>

(which might appear in a help file) would be spaced in the output exactly as you entered it. In
paragraph mode, the above would be output as “Variable name mean standard error”, meaning that
it would all run together. On the other hand, the text

The two main uses of SMCL are in the programs you compose and in the help files
you write to document them, although SMCL may be used in any context.
Everything Stata displays on the screen is processed by SMCL.

would display as a nicely formatted paragraph in paragraph mode.

In mode 3, as-is mode, SMCL directives are not interpreted. {title:...}, for instance, has no
special meaning—it is just the characters open brace, t, i, and so on. If {title:...} appeared in
SMCL input text,

{title:My Title}
it would be displayed exactly as it appears: \{title:My Title\}. In as-is mode, SMCL just displays text as it was entered. As-is mode is useful only for those wishing to document how SMCL works because, with as-is mode, they can show examples of what SMCL input looks like.

Those are the three modes, and the most important of them are the first two, the SMCL modes, and the single most important mode is SMCL line mode—mode 1. Line mode is the mother of all modes in that SMCL continually returns to it, and you can get to the other modes only from line mode. For instance, to enter paragraph mode, you use the \{p\} directive, and you use it from line mode, although you typically do not think of that. Paragraphs end when SMCL encounters a blank line, and SMCL then returns to line mode. Consider the following lines appearing in some help file:

\{p\}
The two main uses of SMCL are in the programs you compose and the help files you write to document them, although SMCL may be used in any context. Everything Stata displays on the screen is processed by SMCL.

\{p\}
Your first encounter with SMCL was probably the Stata session...

Between the paragraphs above, SMCL returned to line mode because it encountered a blank line. SMCL stayed in paragraph mode as long as the paragraph continued without a blank line, but once the paragraph ended, SMCL returned to line mode. There are ways of ending paragraphs other than using blank lines, but they are the most common. Regardless of how paragraphs end, SMCL returns to line mode.

In another part of our help file, we might have

\{p\}
SMCL, which stands for Stata Markup and Control Language and is pronounced "smickle", is Stata’s output language.
SMCL directives, for example, the \{c -(\it:...{c )-\} in the following,
    One can output \{it:italics\} using SMCL
\{p\} affects how output appears: ...

Between the paragraphs, SMCL entered line mode (again, because SMCL encountered a blank line), so the “One can output…” part will appear as you have spaced it, namely, indented. It will appear that way because SMCL is in line mode.

The other mode is invoked using the \{asis\} directive and does not end with a blank line. It continues until you enter the \{smcl\} directive, and here \{smcl\} must be followed by a carriage return. You may put a carriage return at the end of the \{asis\} directive—it will make no difference—but to return to SMCL line mode, you must put a carriage return directly after the \{smcl\} directive.

To summarize, when dealing with SMCL, begin by assuming that you are in line mode; you almost certainly will be. If you wish to enter a paragraph, you will use the \{p\} directive, but once the paragraph ends, you will be back in line mode and ready to start another paragraph. If you want to enter as-is mode, perhaps to include a piece of text output, use the \{asis\} directive, and at the end of the piece, use the \{smcl\}(carriage return) directive to return to line mode.

**Command summary—general syntax**

Pretend that \{xyz\} is a SMCL directive, although it is not. \{xyz\} might have any of the following syntaxes:

Syntax 1: \{xyz\}

Syntax 2: \{xyz:text\}
Syntax 3: `{xyz args}`

Syntax 4: `{xyz args{text}}`

Syntax 1 means “do whatever it is that `{xyz}` does”. Syntax 2 means “do whatever it is that `{xyz}` does, do it on the text `text`, and then stop doing it”. Syntax 3 means “do whatever it is that `{xyz}` does, as modified by `args`”. Finally, syntax 4 means “do whatever it is that `{xyz}` does, as modified by `args`, do it on the text `text`, and then stop doing it”.

Not every SMCL directive has all four syntaxes, and which syntaxes are allowed is made clear in the descriptions below.

In syntaxes 3 and 4, `text` may contain other SMCL directives, so the following is valid:

```
{center:The use of `{ul:SMCL}` in help files}
```

The `text` of one SMCL directive may itself contain other SMCL directives. However, not only must the braces match, but they must match on the same physical (input) line. Typing

```
{center:The use of `{ul:SMCL}` in help files}
```

is correct, but

```
{center:The use of `{ul:SMCL}` in help files}
```

is an error. When SMCL encounters an error, it simply displays the text in the output it does not understand, so the result of making the error above would be to display

```
{center:The use of SMCL in help files}
```

SMCL understood `{ul:...}` but not `{center:...}` because the braces did not match on the input line, so it displayed only that part. If you see SMCL directives in your output, you have made an error.
Help file preprocessor directive for substituting repeated material

INCLUDE help arg follows syntax 3.

INCLUDE specifies that SMCL substitute the contents of a file named arg.ihlp. This is useful when you need to include the same text multiple times. This substitution is performed only when the file is viewed using help.

Example:
We have several commands that accept the replace option. Instead of typing the description under Options of each help file, we create the file replace.ihlp, which contains something like the following:

```{* 01apr2005}{...}
{phang}
{opt replace} overwrite existing {it:filename}{p_end}
```

To include the text in our help file, we type

```
INCLUDE help replace
```

Formatting directives for use in line and paragraph modes

{sf}, {it}, and {bf} follow syntaxes 1 and 2.

These directives specify how the font is to appear. {sf} indicates standard face, {it} italic face, and {bf} boldface.

Used in syntax 1, these directives switch to the font face specified, and that rendition will continue to be used until another one of the directives is given.

Used in syntax 2, they display text in the specified way and then switch the font face back to whatever it was previously.

Examples:
the value of {it}varlist {sf}may be specified ...

the value of {it:varlist} may be specified ...

{input}, {error}, {result}, and {text} follow syntaxes 1 and 2.

These directives specify how the text should be rendered: in the style that indicates user input, an error, a calculated result, or the text around calculated results.

These styles are often rendered as color. In the Results window, on a white background, Stata by default shows input in black and bold, error messages in red, calculated results in black and bold, and text in black. However, the relationship between the real colors and {input}, {error}, {result}, and {text} may not be the default (the user could reset it), and, in fact, these renditions may not be shown in color at all. The user might have set {result}, for instance, to show in yellow, or in highlight, or in something else. However the styles are rendered, SMCL tries to distinguish among {input}, {error}, {result}, and {text}.

Examples:
{text}the variable mpg has mean {result:21.3} in the sample.
{text}mpg {c |} {result}21.3
{text}mpg {c |} {result:21.3}
{error:variable not found}
{inp}, {err}, {res}, and {txt} follow syntaxes 1 and 2.

These four commands are synonyms for {input}, {error}, {result}, and {text}.

Examples:
{txt} the variable mpg has mean {res:21.3} in the sample.
{txt} mpg {c |} {res:21.3}
{txt} mpg {c |} {res:21.3}
{err:variable not found}

{cmd} follows syntaxes 1 and 2.

{cmd} is similar to the “color” styles and is the recommended way to show Stata commands in help files. Do not confuse {cmd} with {inp}. {inp} is the way commands actually typed are shown, and {cmd} is the recommended way to show commands you might type. We recommend that you present help files in terms of {txt} and use {cmd} to show commands; use any of {sf}, {it}, or {bf} in a help file, but we recommend that you not use any of the “colors” {inp}, {err}, or {res}, except where you are showing actual Stata output.

Example:
When using the {cmd:summarize} command, specify ...

{cmdab: text1: text2} follows a variation on syntax 2 (note the double colons).

{cmdab} is the recommended way to show minimum abbreviations for Stata commands and options in help files; text1 represents the minimum abbreviation, and text2 represents the rest of the text. When the entire command or option name is the minimum abbreviation, you may omit text2 along with the extra colon. {cmdab: text} is then equivalent to {cmd: text}; it makes no difference which you use.

Examples:
{cmdab: su:mmarize} [{it:varlist}] [{it:weight}] [{cmdab:if} {it:exp}]
the option {cmdab:ef:orm}{cmd:({it:varname})} ...

{o|p|t option}, {o|p|t option (arg)}, {o|p|t option(a,b)}, and {o|p|t option(a|b)} follow syntax 3; alternatives to using {cmd}.

{o|p|t option1:option2}, {o|p|t option1:option2(arg)}, {o|p|t option1:option2(a,b)}, and {o|p|t option1:option2(a|b)} follow syntaxes 3 and 4; alternatives to using {cmdab}.

{o|p|t} is the recommended way to show options. {o|p|t} allows you to easily include arguments.

SMCL directive ... is equivalent to typing ...

<table>
<thead>
<tr>
<th>SMCL directive ...</th>
<th>is equivalent to typing ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
<tr>
<td>{o</td>
<td>p</td>
</tr>
</tbody>
</table>

{option1} represents the minimum abbreviation, and {option2} represents the rest of the text.

a, b and a|b may have any number of elements. Available elements that are displayed in {cmd} style are ,, =, :, *, %, and (). Several elements are displayed in plain text style: |, { }, and [].

Also, {opt option (arg)} is equivalent to {opt}, except that arg is displayed as a link to help; see Link directives for use in line and paragraph modes for more details.
Examples:
{opt replace}
{opt bseunit(varname)}
{opt f:ormat}
{opt sep:arator(#)}

{hilite} and {hi} follow syntaxes 1 and 2.
{hilite} and {hi} are synonyms. {hilite} is the recommended way to highlight (draw attention to) something in help files. You might highlight, for example, a reference to a manual, the Stata Journal, or a book.

Examples:
see {hilite:[R] anova} for more details.
see {hi:[R] anova} for more details.

{ul} follows syntaxes 2 and 3.
{ul on} starts underlining mode. {ul off} ends it. {ul:text} underlines text.

Examples:
You can {ul on}underline{ul off} this way or
you can {ul:underline} this way

{*} follows syntaxes 2 and 4.
{*} indicates a comment. What follows it (inside the braces) is ignored.

Examples:
{* this text will be ignored}
{*:as will this}

{hline} follows syntaxes 1 and 3.
{hline} (syntax 1) draws a horizontal line the rest of the way across the page.
{hline #} (syntax 3) draws a horizontal line of # characters.
{hline} (either syntax) is generally used in line mode.

Examples:
{hline}
{hline 20}

{.-} follows syntax 1.
{.-} is a synonym for {hline} (syntax 1).

Example:
{.-}

{dup #:text} follows syntax 4.
{dup} repeats text # times.

Examples:
{dup 20:A}
{dup 20:ABC}
{char code} and {c code} are synonyms and follow syntax 3.

These directives display the specified characters that otherwise might be difficult to type on your keyboard. See Displaying characters using ASCII and extended ASCII codes below.

Examples:
C{c o’}rdoba es una joya arquitect{c o’}nica.
{c S|}57.20
The ASCII character 206 in the current font is {c 206}
The ASCII character 5a (hex) is {c 0x5a}
{c -(} is open brace and {c )-} is close brace

{reset} follows syntax 1.
{reset} is equivalent to coding {txt}{sf}.
Example:
{reset}

Link directives for use in line and paragraph modes

All the link commands share the feature that when syntax 4 is allowed,

Syntax 4: {xyz args:text}
then syntax 3 is also allowed,

Syntax 3: {xyz args}

and if you specify syntax 3, Stata treats it as if you specified syntax 4, inserting a colon and then repeating the argument. For instance, {help} is defined below as allowing syntaxes 3 and 4. Thus the directive

{help summarize}

is equivalent to the directive

{help summarize:summarize}

Coding {help summarize} or {help summarize:summarize} both display the word summarize, and if the user clicks on that, the action of help summarize is taken. Thus you might code

See help for {help summarize} for more information.

This would display “See help for summarize for more information” and make the word summarize a link. To make the words describing the action different from the action, use syntax 4.

You can also {help summarize:examine the summary statistics} if you wish.

which results in “You can also examine the summary statistics if you wish.”

The link directives, which may be used in either line mode or paragraph mode, are the following:

{help args[:text]} follows syntaxes 3 and 4.

{help} displays args as a link to help args; see [R] help. If you also specify the optional :text, text is displayed instead of args, but you are still directed to the help file for args.

Examples:
{help epitab}
{help summarize:the mean}
{helpb args[:text]} follows syntaxes 3 and 4.
   {helpb} is equivalent to {help}, except that args or text is displayed in boldface.

   Examples:
   {helpb summarize}
   {helpb generate}

{manhelp args1 args2[:text]} follows syntaxes 3 and 4.
   {manhelp} displays [args2] args1 as a link to help args1; thus our first example below would display [R] summarize as a link to help summarize. Specifying the optional :text displays text instead of args1, but you are still directed to the help file for args1.

   Examples:
   {manhelp summarize R}
   {manhelp weight U:14 Language syntax}
   {manhelp graph_twoway G:graph twoway}

{manhelpi args1 args2[:text]} follows syntaxes 3 and 4.
   {manhelpi} is equivalent to {manhelp}, except that args or text is displayed in italics.

   Examples:
   {manhelpi twoway_options G}
   {manhelpi mata M:Mata Reference Manual}

{help args##markername[\viewername] [:text]} and {marker markername} follow syntax 3.
   They let the user jump to a specific location within a file, not just to the top of the file. {help args##markername} displays args##markername as a link that will jump to the location marked by {marker markername}. Specifying the optional \viewername will display the results of {marker markername} in a new Viewer window named viewername; _new is a valid viewername that assigns a unique name for the new Viewer. Specifying the optional :text displays text instead of args##markername. args represents the name of the file where the {marker} is located. If args contains spaces, be sure to specify it within quotes.

   We document the directive as {help ...}; however, view, news, net, ado, and update may be used in place of help, although you would probably want to use only help or view.

   Examples:
   {pstd}You can change the style of the text using the {cmd} directive; see {help example##cmd} below.
   You can underline a word or phrase with the {ul} directive; see {help example##ul:below}.

   {marker cmd}{...}
   {phang}{cmd} follows syntaxes 1 and 2.{break}
   {cmd} is another style not unlike the ...

   {marker ul}{...}
   {phang}{ul} follows syntaxes 2 and 3.{break}
   {ul on} starts underlining mode. {ul} ...

{help_d:text} follows syntax 2.
   {help_d} displays text as a link that will display a help dialog box from which the user may obtain interactive help on any Stata command.

   Example:
   ... using the {help_d:help system} ...
{newvar[:args]} follows syntaxes 1 and 2. 
{newvar} displays newvar as a link to help newvar. If you also specify the optional :args, Stata concatenates args to newvar to display newvarargs.

Examples:
{newvar}
{newvar:2}

{var[:args]} and {varname[:args]} follow syntaxes 1 and 2. 
{var} and {varname} display varname as a link to help varname. If you also specify the optional :args, Stata concatenates args to varname to display varnameargs.

Examples:
{var}
{var:1}
{varname}
{varname:2}

{vars[:args]} and {varlist[:args]} follow syntaxes 1 and 2. 
{vars} and {varlist} display varlist as a link to help varlist. If you also specify the optional :args, Stata concatenates args to varlist to product varlistargs.

Examples:
{vars}
{vars:1}
{varlist}
{varlist:2}

{depvar[:args]} follows syntaxes 1 and 2. 
{depvar} displays depvar as a link to help depvar. If you also specify the optional :args, Stata concatenates args to depvar to display depvarargs.

Examples:
{depvar}
{depvar:1}

{depvars[:args]} and {depvarlist[:args]} follow syntaxes 1 and 2. 
{depvars} and {depvarlist} display depvarlist as a link to help depvarlist. If you also specify the optional :args, Stata concatenates args to depvarlist to display depvarlistargs.

Examples:
{depvars}
{depvars:1}
{depvarlist}
{depvarlist:2}

{indepvars[:args]} follows syntaxes 1 and 2. 
{indepvars} displays indepvars as a link to help varlist. If you also specify the optional :args, Stata concatenates args to indepvars to display indepvarsargs.

Examples:
{indepvars}
{indepvars:1}
{ifin} follows syntax 1.
   {ifin} displays [if] and [in], where if is a link to the help for the if qualifier and in is a link to the help for the in qualifier.
Example:
   {ifin}

{weight} follows syntax 1.
   {weight} displays [weight], where weight is a link to the help for the weight specification.
Example:
   {weight}

{dtype} follows syntax 1.
   {dtype} displays [type], where type is a link to help data types.
Example:
   {dtype}

{search args[:text]} follows syntaxes 3 and 4.
   {search} displays text as a link that will display the results of search on args; see [R] search.
Examples:
   {search anova:click here} for the latest information on ANOVA
   Various programs are available for {search anova}

{search_d:} follows syntax 2.
   {search_d} displays text as a link that will display a Keyword Search dialog box from which the user can obtain interactive help by entering keywords of choice.
Example:
   ... using the {search_d:search system} ...

{dialog args[:text]} follows syntaxes 3 and 4.
   {dialog} displays text as a link that will launch the dialog box for args. args must contain the name of the dialog box and may optionally contain , message(string), where string is the message to be passed to the dialog box.
Example:
   ... open the {dialog regress:regress dialog box} ...

{browse args[:text]} follows syntaxes 3 and 4.
   {browse} displays text as a link that will launch the user's browser pointing at args. Because args is typically a URL containing a colon, args usually must be specified within quotes.
Example:
   ... you can {browse "http://www.stata.com":visit the Stata website} ...

{view args[:text]} follows syntaxes 3 and 4.
   {view} displays text as a link that will present in the Viewer the filename args. If args is a URL, be sure to specify it within quotes. {view} is seldom used in a SMCL file (such as a help file) because you will seldom know of a fixed location for the file unless it is a URL. {view} is sometimes used from programs because the program knows the location of the file it created.
   {view} can also be used with {marker}; see {help args##markernamem|viewernamem[:text]} and {marker markernamem}, earlier in this section.
Examples:

see {view "http://www.stata.com/man/readme.smcl"}
display '{view "newfile":click here} to view the file created'}

{view_d:} follows syntax 2.

{view_d} displays text as a link that will display the Choose File to View dialog box in which the user may type the name of a file or a URL to be displayed in the Viewer.

Example:

{view_d:Click here} to view your current log

{manpage args[:text]} follows syntaxes 3 and 4.

{manpage} displays text as a link that will launch the user’s PDF viewer pointing at args. args are a Stata manual (such as R or SVY) and a page number. The page number is optional. If the page number is not specified, the PDF viewer will open to the first page of the file.

Example:
The formulas are given on {manpage R 342:page 342 of [R] manual}.

{mansection args[:text]} follows syntaxes 3 and 4.

{mansection} displays text as a link that will launch the user’s PDF viewer pointing at args. args are a Stata manual (such as R or SVY) and a named destination within that manual (such as predict or regress postestimation). The named destination is optional. If the named destination is not specified, the PDF viewer will open to the first page of the file.

Example:

See {mansection R clogitpostestimation:[R] clogit postestimation}.

{manlink man entry} and {manlinki man entry} follow syntax 3.

{manlink} and {manlinki} display man and entry using the {mansection} directive as a link that will launch the user’s PDF viewer pointing at that manual entry. man is a Stata manual (such as R or SVY) and entry is the name of an entry within that manual (such as predict or regress postestimation). The named destination should be written as it appears in the title of the manual entry.

<table>
<thead>
<tr>
<th>SMCL directive</th>
<th>is equivalent to typing</th>
</tr>
</thead>
<tbody>
<tr>
<td>{manlink man entry}</td>
<td>{bf:{mansection man entry_ns:[man] entry}}</td>
</tr>
<tr>
<td>{manlinki man entry}</td>
<td>{bf:{mansection man entry_ns:[man] {it:entry}}}</td>
</tr>
</tbody>
</table>

entry\_ns is entry with the following characters removed: space, left and right quotes (‘ and ’), #, $, ~, {, }, [, and ].

{news:} follows syntax 2.

{news} displays text as a link that will display in the Viewer the latest news from http://www.stata.com.

{news} can also be used with {marker}; see {help args##markernamem[|viewername] [:text]} and {marker markernamem} earlier in this section.

Example:

For the latest NetCourse offerings, see the {news:news}.
{\texttt{net \texttt{args[::text]}}} follows syntaxes 3 and 4.

{\texttt{net}} displays \texttt{args} as a link that will display in the Viewer the results of \texttt{net \texttt{args}}; see \cite{R net}. Specifying the optional \texttt{:text}, displays \texttt{text} instead of \texttt{args}. For security reasons, \texttt{net get} and \texttt{net install} cannot be executed in this way. Instead, use \{\texttt{net describe \ldots}\} to show the page, and from there, the user can click on the appropriate links to install the materials. Whenever \texttt{args} contains a colon, as it does when \texttt{args} is a URL, be sure to enclose \texttt{args} within quotes.

\{\texttt{net cd .::text}\} displays \texttt{text} as a link that will display the contents of the current \texttt{net} location. \{\texttt{net}\} can also be used with \{\texttt{marker}\}; see \{\texttt{help args##markername[|viewername][::text]}\} and \{\texttt{marker markername}\}, earlier in this section.

**Examples:**

programs are available from \{\texttt{net "from http://www.stata.com":Stata}\}
Nicholas Cox has written a series of matrix commands which you can obtain by \{\texttt{net "describe http://www.stata.com/stb/stb56/dm79":clicking here}\}.

\{\texttt{net\_d::text}\} follows syntax 2.

\{\texttt{net\_d}\} displays \texttt{text} as a link that will display a Keyword Search dialog box from which the user can search the Internet for additions to Stata.

**Example:**
To search the Internet for the latest additions to Stata available, \{\texttt{net\_d:click here}\}.

\{\texttt{netfrom\_d::text}\} follows syntax 2.

\{\texttt{netfrom\_d}\} displays \texttt{text} as a link that will display a Choose Download Site dialog box into which the user may enter a URL and then see the contents of the site. This directive is seldom used.

**Example:**
If you already know the URL, \{\texttt{netfrom\_d:click here}\}.

\{\texttt{ado \texttt{args[::text]}}\} follows syntaxes 3 and 4.

\{\texttt{ado}\} displays \texttt{text} as a link that will display in the Viewer the results of \texttt{ado \texttt{args}}; see \cite{R ado}. For security reasons, \texttt{ado uninstall} cannot be executed in this way. Instead, use \{\texttt{ado describe \ldots}\} to show the package, and from there, the user can click to uninstall (delete) the material.

\{\texttt{ado}\} can also be used with \{\texttt{marker}\}; see \{\texttt{help args##markername[|viewername][::text]}\} and \{\texttt{marker markername}\}, earlier in this section.

**Example:**
You can see the user-written packages you have installed (and uninstall any that you wish) by \{\texttt{ado dir:clicking here}\}.

\{\texttt{ado\_d::text}\} follows syntax 2.

\{\texttt{ado\_d}\} displays \texttt{text} as a link that will display a Search Installed Programs dialog box from which the user can search for user-written routines previously installed (and uninstall them if desired).

**Example:**
You can search the user-written ado-files you have installed by \{\texttt{ado\_d:clicking here}\}.

\{\texttt{update \texttt{args[::text]}}\} follows syntaxes 3 and 4.

\{\texttt{update}\} displays \texttt{text} as a link that will display in the Viewer the results of \texttt{update \texttt{args}}; see \cite{R update}. If \texttt{args} contains a URL, be careful to place the \texttt{args} in quotes.
args can be omitted because the update command is valid without arguments. \{update:\text\} is really the best way to use the \{update\} directive because it allows the user to choose whether and from where to update their Stata.

\{update\} can also be used with \{marker\}; see \{help args\#markername[\|viewernam[[:text]]\} and \{marker markername\}, earlier in this section.

**Examples:**
Check whether your Stata is \{update:up to date\}.
Check whether your Stata is \{update "from http://www.stata.com":up to date\}.

\{update\_d:\text\} follows syntax 2.
\{update\_d\} displays \text as a link that will display a Choose Official Update Site dialog box into which the user may type a source (typically http://www.stata.com, but perhaps a local CD drive) from which to install official updates to Stata.

**Example:**
If you are installing from CD or some other source, 
\{update\_d:click here\}.

\{back:\text\} follows syntax 2.
\{back\} displays \text as a link that will take an action equivalent to pressing the Viewer’s Back button.

**Example:**
\{back:go back to the previous page\}

\{clearmore:\text\} follows syntax 2.
\{clearmore\} displays \text as a link that will take an action equivalent to pressing Stata’s Clear–more–Condition button. \{clearmore\} is of little use to anyone but the developers of Stata.

**Example:**
\{clearmore: {hline 2}more{hline 2}\}

\{stata args[[:text]]\} follows syntaxes 3 and 4.
\{stata\} displays \text as a link that will execute the Stata command \text in the Results window. Stata will first ask before executing a command that is displayed in a web browser. If \text (the Stata command) contains a colon, remember to enclose the command in quotes.

**Example:**
... \{stata summarize mpg:to obtain the mean of mpg\}...

Remember, like all SMCL directives, \{stata\} can be used in programs as well as files. Thus you could code

\text
or, if you were in the midst of outputting a table,
\text

However, it is more likely that, rather than being hardcoded, the variable name would be in a macro, say, \text:\nm
\text
Here you probably would not know how many blanks to put after the variable name because it could be of any length. Thus you might code

\text
thus allocating 12 spaces for the variable name, which would be followed by a blank and the vertical bar. Then you would want to allow for a ‘vn’ longer than 12 characters:

```
local vna = abbrev('vn',12)
di "{ralign 12:{stata summ 'vn':'vna'}} {c |}"
```

There you have a line that will output a part of a table, with the linked variable name on the left and with the result of clicking on the variable name being to `summ 'vn'`. Of course, you could make the action whatever else you wanted.

```
{matacmd args[:text]} follows syntaxes 3 and 4.
{matacmd} works the same as `{stata}`, except that it submits a command to Mata. If Mata is not already active, the command will be prefixed with `mata` to allow Stata to execute it.
```

### Formatting directives for use in line mode

**{title:}** (carriage return) follows syntax 2.

*{title:*} displays text as a title. `{title:...}` should be followed by a carriage return and, usually, by one more blank line so that the title is offset from what follows. (In help files, we precede titles by two blank lines and follow them by one.)

**Example:**

```
{title:Command summary -- general syntax}
```

```
Pretend that `{cmd:{c -({xyz}c )-}}` is a SMCL directive, although ...
```

*{center:*} and *{centre:*} follow syntax 2.

*{center #:} and *{centre #:} follow syntax 4.

*{center:*} and *{centre:*} are synonyms; they center the text on the line. *{center:*} should usually be followed by a carriage return; otherwise, any text that follows it will appear on the same line. With **syntax 4**, the directives center the text in a field of width #.

**Examples:**

```
{center:This text will be centered}
{center:This text will be centered} and this will follow it
{center 60:This text will be centered within a width of 60 columns}
```

*{rcenter:*} and *{rcentre:*} follow syntax 2.

*{rcenter #:} and *{rcentre #:} follow syntax 4.

*{rcenter:*} and *{rcentre:*} are synonyms. *{rcenter} is equivalent to *{center}, except that text is displayed one space to the right when there are unequal spaces left and right. *{rcenter:*} should be followed by a carriage return; otherwise, any text that follows it will appear on the same line. With **syntax 4**, the directives center the text in a field of width #.

**Example:**

```
{rcenter:This text will be centered right one character}
```

*{right:*} follows syntax 2.

*{right:*} displays text with its last character aligned on the right margin. *{right:*} should be followed by a carriage return.

**Examples:**

```
{right:This is right-aligned}
{right:This is shifted left one character}
```
{lalign #:text} and {ralign #:text} follow syntax 4.  
{lalign} left-aligns text in a field # characters wide, and {ralign} right-aligns text in a field # characters wide.

Example:
{lalign 12:mpg}{ralign 15:21.2973}

{dlgtab [# [#]]:text} follows syntaxes 2 and 4.
{dlgtab} displays text as a dialog tab. The first # specifies how many characters to indent the dialog tab from the left-hand side, and the second # specifies how much to indent from the right-hand side. The default is {dlgtab 4 2:text}.

Examples:
{dlgtab:Model}
{dlgtab 8 2:Model}

{...} follows syntax 1.
{...} specifies that the next carriage return be treated as a blank.

Example:
Sometimes you need to type a long line and, while {...}
that is fine with SMCL, some word processors balk. {...}
In line mode, the above will appear as one long line to SMCL.

{col #} follows syntax 3.
{col #} skips forward to column #. If you are already at or beyond that column in the output, then {col #} does nothing.

Example:
mpg{col 20}21.3{col 30}5.79

{space #} follows syntax 3.
{space} is equivalent to typing # blank characters.

Example:
20.5{space 20}17.5

{tab} follows syntax 1.
{tab} has the same effect as typing a tab character. Tab stops are set every eight spaces.

Examples:
{tab}This begins one tab stop in
{tab}{tab}This begins two tab stops in

Note: SMCL also understands tab characters and treats them the same as the {tab} command, so you may include tabs in your files.

Formatting directives for use in paragraph mode

{p} follows syntax 3. The full syntax is {p # # # #}.
{p # # # #} enters paragraph mode. The first # specifies how many characters to indent the first line; the second #, how much to indent the second and subsequent lines; the third #, how much to bring in the right margin on all lines; and the fourth # is the total width for the paragraph.
Numbers, if not specified, default to zero, so typing {p} without numbers is equivalent to typing {p 0 0 0 0}, {p #} is equivalent to {p 0 0 0 0}, and so on. A zero for the fourth # means use the default paragraph width; see set linesize in [R] log. {p} (with or without numbers) may be followed by a carriage return or not; it makes no difference.
Paragraph mode ends when a blank line is encountered, the \{p_end\} directive is encountered, or \{smcl\}(carriage return) is encountered.

Examples:
\{p\}
\{p 4\}
\{p 0 4\}
\{p 8 8 60\}

Note concerning paragraph mode: In paragraph mode, you can have either one space or two spaces at the end of sentences, following the characters ‘.’, ‘?’ , ‘!’ , and ‘:’. In the output, SMCL puts two spaces after each of those characters if you put two or more spaces after them in your input, or if you put a carriage return; SMCL puts one space if you put one space. Thus

\{p\}
Dr. Smith was near panic. He could not reproduce the result.
Now he wished he had read about logging output in Stata.

will display as

Dr. Smith was near panic. He could not reproduce the result. Now he wished he had read about logging output in Stata.

Several shortcut directives have also been added for commonly used paragraph mode settings:

| SMCL directive ...         | is equivalent to typing ...
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>{pstd}</td>
<td>{p 4 4 2}</td>
</tr>
<tr>
<td>{psee}</td>
<td>{p 4 13 2}</td>
</tr>
<tr>
<td>{phang}</td>
<td>{p 4 8 2}</td>
</tr>
<tr>
<td>{pmore}</td>
<td>{p 8 8 2}</td>
</tr>
<tr>
<td>{pin}</td>
<td>{p 8 8 2}</td>
</tr>
<tr>
<td>{phang2}</td>
<td>{p 8 12 2}</td>
</tr>
<tr>
<td>{pmore2}</td>
<td>{p 12 12 2}</td>
</tr>
<tr>
<td>{pin2}</td>
<td>{p 12 12 2}</td>
</tr>
<tr>
<td>{phang3}</td>
<td>{p 12 16 2}</td>
</tr>
<tr>
<td>{pmore3}</td>
<td>{p 16 16 2}</td>
</tr>
<tr>
<td>{pin3}</td>
<td>{p 16 16 2}</td>
</tr>
</tbody>
</table>

\{p_end\} follows syntax 1.
\{p_end\} is a way of ending a paragraph without having a blank line between paragraphs. \{p_end\} may be followed by a carriage return or not; it will make no difference in the output.

Example:
\{p_end\}

\{p2colset \# \# \#\} follows syntax 3.
\{p2col \[\# \# \#\] : [first_column_text] \} \[second_column_text\] follows syntaxes 2 and 4.
\{p2line \[\# \#\]\} follows syntaxes 1 and 3.
\{p2colreset\} follows syntax 1.
\{p2colset\} sets column spacing for a two-column table. The first \# specifies the beginning position of the first column, the second \# specifies the placement of the second column, the third \# specifies the placement for subsequent lines of the second column, and the last \# specifies the number to indent from the right-hand side for the second column.

\{p2col\} specifies the rows that make up the two-column table. Specifying the optional numbers redefines the numbers specified in \{p2colset\} for this row only. If the first_column_text or the second_column_text is not specified, the respective column is left blank.
draws a dashed line for use with a two-column table. The first # specifies the left indentation, and the second # specifies the right indentation. If no numbers are specified, the defaults are based on the numbers provided in \{p2colset\}.

\{p2colreset\} restores the \{p2col\} default values.

**Examples:**
\{p2colset 9 26 27 2\}{...}
\{p2col:{keyword}\}rules{p_end}
\{p2line\}
\{p2col:{opt nonm:issing}\}all nonmissing values not changed by the rules{p_end}
\{p2col 7 26 27 2:* {opt m:issing}\}all missing values not changed by the rules{p_end}
\{p2line\}
\{p2colreset\}{...}

\{synoptset \[#\] \{tabbed \notes\}\} follows syntaxes 1 and 3.
\{synopthdr: \{first\_column\_header\}\} follows syntaxes 1 and 2.
\{syntab: \text\} follows syntax 2.
\{synopt: [\{first\_column\_text\}][\{second\_column\_text\}]\} follows syntax 2.
\{p2coldent: [\{first\_column\_text\}][\{second\_column\_text\}]\} follows syntax 2.
\{synoptline\} follows syntax 1.

\{synoptset\} sets standard column spacing for a two-column table used to document options in syntax diagrams. \# specifies the width of the first column; the width defaults to 20 if \# is not specified. The optional argument \tabbed\ specifies that the table will contain headings or “tabs” for sets of options. The optional argument \notes\ specifies that some of the table entries will have footnotes and results in a larger indentation of the first column than the \tabbed\ argument implies.

\{synopthdr\} displays a standard header for a syntax-diagram-option table. \first\_column\_header\ is used to title the first column in the header; if \first\_column\_header\ is not specified, the default title “options” is displayed. The second column is always titled “Description”.

\{syntab\} displays \text\ positioned as a subheading or “tab” in a syntax-diagram-option table.

\{synopt\} specifies the rows that make up the two-column table; it is equivalent to \{p2col\} (see above).

\{p2coldent\} is the same as \{synopt\}, except the \first\_column\_text\ is displayed with the standard indentation (which may be negative). The \second\_column\_text\ is displayed in paragraph mode and ends when a blank line, \{p\_end\}, or a carriage return is encountered. The location of the columns is determined by a prior \{synoptset\} or \{p2colset\} directive.

\{synoptline\} draws a horizontal line that extends to the boundaries of the previous \{synoptset\} or, less often, \{p2colset\} directive.

**Examples:**
\{synoptset 21 \tabbed\}{...}
\{synopthdr\}
\{synoptline\}
\{syntab:Model\}
\{p2coldent: * \{opt \asorb\(varname\)\}\}categorical variable to be absorbed{p_end}
\{synopt: {opt clear}\}\reminder that untransposed data will be lost if not previously saved{p_end}
\{synoptline\}
\{p2colreset\}{...}
{bind: text} follows syntax 2.
{bind: ...} keeps text together on a line, even if that makes one line of the paragraph unusually short. {bind: ...} can also be used to insert one or more real spaces into the paragraph if you specify text as one or more spaces.

Example:
Commonly, bind is used {bind: to keep words together} on a line.

{break} follows syntax 1.
{break} forces a line break without ending the paragraph.

Example:
{p 4 8 4}
{it: Example:}{break}
Commonly,...

Directive for entering the as-is mode

{asis} follows syntax 1.
{asis} begins as-is mode, which continues until {smcl}(carriage return) is encountered. {asis} may be followed by a carriage return or not; it makes no difference, but {smcl} must be immediately followed by a carriage return. {smcl} returns SMCL to line mode. No other SMCL commands are interpreted in as-is mode.

Inserting values from constant and current-value class

The {ccl} directive outputs the value contained in a constant and current-value class (c()) object. For instance, {ccl pi} provides the value of the constant pi (3.14159...) contained in c(pi). See [P] creturn for a list of all the available c() objects.

Displaying characters using ASCII and extended ASCII codes

The {char} directive—synonym {c}—allows you to output any ASCII or extended ASCII character in Latin1 encoding. Extended ASCII characters in Latin1 encoding are converted to the equivalent Unicode characters in the UTF-8 encoding. For instance, {c 232} is equivalent to typing the letter ê because extended ASCII code 232 in Latin1 is defined as the letter “e” with a grave accent. You may also type the Unicode character è (code point \u00e8) directly.

You can get to all the ASCII and extended ASCII characters in Latin1 encoding by typing {c #}, where # is between 1 and 255. Or, if you prefer, you can type {c 0x#}, where # is a hexadecimal number between 1 and ff. Thus {c 0x6a} is also j because the hexadecimal number 6a is equal to the decimal number 106.

Also, so that you do not have to remember the numbers, {c} provides special codes for characters that are, for one reason or another, difficult to type. These include

{c $ |} $ (dollar sign)
{c 'g} ‘ (open single quote)
{c -{ |} { (left curly brace)
{c )-} } (right curly brace)
{c S|} and {c ’g} are included not because they are difficult to type or cause SMCL any problems but because in Stata display statements, they can be difficult to display, since they are Stata’s macro substitution characters and tend to be interpreted by Stata. For instance,

```
. display "shown in $US"
shown in
```
drops the $US part because Stata interpreted $US as a macro, and the global macro was undefined. A way around this problem is to code

```
. display "shown in {c S|}US"
shown in $US
```

{c -()} and {c )-} are included because { and } are used to enclose SMCL directives. Although { and } have special meaning to SMCL, SMCL usually displays the two characters correctly when they do not have a special meaning. SMCL follows the rule that, when it does not understand what it thinks ought to be a directive, it shows what it did not understand in unmodified form. Thus

```
. display "among the alternatives {1, 2, 4, 7}"
among the alternatives {1, 2, 4, 7}
```

works, but

```
. display "in the set {result}"
in the set
```
does not because SMCL interpreted {result} as a SMCL directive to set the output style (color) to that for results. The way to code the above is to type

```
. display "in the set {c -}result{c )-}"
in the set {result}
```

SMCL also provides the following line-drawing characters:

- \{c -\} a wide dash character
- \{c \} a tall | character
- \{c +\} a wide dash on top of a tall |
- \{c TT\} \(\top\) a top T
- \{c BT\} \(\bot\) a bottom T
- \{c LT\} \(\uparrow\) a left T
- \{c RT\} \(\downarrow\) a right T
- \{c TLC\} \(\langle\) a top-left corner
- \{c TRC\} \(\rangle\) a top-right corner
- \{c BRC\} \(\rangle\) a bottom-right corner
- \{c BLC\} \(\langle\) a bottom-left corner

\{hline\} constructs the line by using the \{c -\} character. The above are not really characters; they are instructions to SMCL to draw lines. The “characters” are, however, one character wide and one character tall, so you can use them as characters in your output. The result is that Stata output that appears on your screen can look like

```
. summarize mpg weight

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
</tbody>
</table>
```
but, if the result is translated into plain text, it will look like

```
. summarize mpg weight

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
</tbody>
</table>
```

because SMCL will be forced to restrict itself to the characters.

Finally, SMCL provides the following Western European characters:

- `{c a'}`  á `{c e'}`  ć `{c i'}`  í `{c o'}`  ó `{c u'}`  ú
- `{c A'}`  Â `{c E'}`  Ê `{c I'}`  Í `{c O'}`  Ô `{c U'}`  Ú
- `{c a'g}` à `{c e'g}`  ç `{c i'g}`  ï `{c o'g}`  ò `{c u'g}`  ù
- `{c A'g}` À `{c E'g}`  Ê `{c I'g}`  Í `{c O'g}`  Ô `{c U'g}`  Ú
- `{c a~}`  à `{c e~}`  ê `{c i~}`  í `{c o~}`  õ `{c u~}`  ú
- `{c A~}`  Á `{c E~}`  Ê `{c I~}`  Í `{c O~}`  Ô `{c U~}`  Ú
- `{c a-}`  à `{c e-}`  è `{c i-}`  í `{c o-}`  ö
- `{c A-}`  Â `{c E-}`  Ê `{c I-}`  Í `{c O-}`  Ô
- `{c a:}`  ã `{c e:}`  ć `{c i:}`  î `{c o:}`  ö `{c u:}`  ú
- `{c A:}`  Â `{c E:}`  Ê `{c I:}`  Í `{c O:}`  Ô `{c U:}`  Ú
- `{c ae}`  æ `{c c,}`  ç `{c n-}`  ñ `{c o/}`  ø `{c y'}`  ý
- `{c AE}`  Å `{c C,}`  ç `{c N-}`  ñ `{c O/}`  Ø `{c Y'}`  Ý
- `{c y:}`  ÿ `{c ss}`  ß `{c r?}`  ¿ `{c r!}`  ¡
- `{c L-}`  £ `{c Y=}`  (yen)

SMCL uses UTF-8 to render the above characters. For instance, `{c e'}` is equivalent to `{c 0xe9}`, if you care to look it up. `{c 0xe9}` will display as é if you are using a Latin1 encoding.

**Advice on using display**

Do not think twice; you can just use SMCL directives in your display statements, and they will work. What we are really talking about, however, is programming, and there are two things to know.

First, remember how display lets you display results as text, as result, as input, and as error, with the abbreviations as txt, as res, as inp, and as err. For instance, a program might contain the lines

```
program ...
...quietly summarize 'varname'
    display as txt "the mean of 'varname' is " as res r(mean)
...end
```

Results would be the same if you coded the display statement

```
display "{txt}the mean of 'varname' is {res}" r(mean)
```

That is, the display directive as txt just sends `{txt}` to SMCL, the display directive as res just sends `{res}` to SMCL, and so on.

However, as err does not just send `{err}`, as err also tells Stata that what is about to be displayed is an error message so that, if output is being suppressed, Stata knows to display this message anyway. For example,

```
display as err "varname undefined"
```
is the right way to issue the error message “varname undefined”.

    display "{err}varname undefined"

would not work as well; if the program’s output were suppressed, the error message would not be displayed because Stata would not know to stop suppressing output. You could code

    display as err "{err}varname undefined"

but that is redundant. display’s as error directive both tells Stata that this is an error message and sends the {err} directive to SMCL. The last part makes output appear in the form of error messages, probably in red. The first part is what guarantees that the error message appears, even if output is being suppressed.

If you think about this, you will now realize that you could code

    display as err "{txt}varname undefined"

to produce an error message that would appear as ordinary text (meaning that it would probably be in black) and yet still display in all cases. Please do not do this. By convention, all error messages should be displayed in SMCL’s {err} (default red) rendition.

The second thing to know is how Stata sets the state of SMCL the instant before display displays its output. When you use display interactively—when you use it at the keyboard or in a do-file—Stata sets SMCL in line mode, font face {sf}, and style {res}. For instance, if you type

    . display 2+2
    4

the 4 will appear in {sf}{res}, meaning in standard font face and in result style, which probably means in black and bold. On the other hand, consider the following:
Here the 4 will appear in `sf{inp}`, meaning that the result is probably also shown in black and bold. However, if your preferences are set to display input differently than results, the output from the program will be different from the interactive output.

When `display` is executed from inside a program, no changes are made to SMCL. SMCL is just left in the mode it happens to be in, and here it happened to be in line mode `{sf}{inp}` because that was the mode it was in after the user typed the command `demonstrate_display`.

This is an important feature of `display` because it means that, in your programs, one `display` can pick up where the last left off. Perhaps you have four or five `display`s in a row that produce the text to appear in a paragraph. The first `display` might begin paragraph mode, and the rest of the `display`s finish it off, with the last `display` displaying a blank line to end paragraph mode. Here it is of great importance that SMCL stay in the mode you left it in between `display`s.

That leaves only the question of what mode SMCL is in when your program begins. You should assume that SMCL is in line mode but make no assumptions about the style (color) `{txt}`, `{res}`, `{err}`, or `{inp}`. Within a program, all `display` commands should be coded as

```stata
    display as ... ...
```

or

```stata
    display "one of {txt}, {res}, {err}, or {inp} ..." ...
```

although you may violate this rule if you really intend one `display` to pick up where another left off. For example,

```stata
    display as text "{p}"
    display "This display violates the rule, but that is all right"
    display "because it is setting a paragraph, and we want all"
    display "these displays to be treated as a whole."
    display "We did follow the rule with the first display in the"
    display "sequence."
    display
    display "Now we are back in line mode because of the blank line"
```

You could even code

```stata
    program example2
    display as text "{p}"
    display "Below we will call a subroutine to contribute a sentence"
    display "to this paragraph being constructed by example2:"
    example2_subroutine
    display "The text that example2_subroutine contributed became"
    display "part of this single paragraph. Now we will end the paragraph."
    display
    end

    program example2_subroutine
    display "This sentence is being displayed by"
    display "example2_subroutine."
    end
```
The result of running this would be

```
.example2
```

Below we will call a subroutine to contribute a sentence to this paragraph being constructed by example2: This sentence is being displayed by example2_subroutine. The text that example2_subroutine contributed became part of this single paragraph. Now we will end the paragraph.

### Advice on formatting help files

Help files are just files named *filename*.sthlp that Stata displays when the user types “help filename”. The first line of a help file should read

```
{smcl}
```

After that, it is a matter of style. To see examples of our style, type

```
.viewsource assert.sthlp     (simple example with a couple of options)
.viewsource centile.sthlp    (example with an options table)
.viewsource regress.sthlp     (example of an estimation command)
.viewsource regress_postestimation.sthlp (example of a postestimation entry)
```

We recommend opening a second Viewer window (one way is to right-click within an existing Viewer and select “Open New Viewer”) to look at the help file and the raw source file side by side.

sortpreserve — Sort within programs

Description

This entry discusses the use of sort (see [D] sort) within programs.

Syntax

```
program [define] program_name [, ... sortpreserve ...]
```

Option

sortpreserve specifies that the program, during its execution, will re-sort the data and that therefore Stata itself should take action to preserve the order of the data so that the order can be reestablished afterward.

sortpreserve is in fact independent of whether a program is byable() but byable() programs often specify this option.

Pretend you are writing the program myprog and that, in performing its calculations, it needs to sort the data. It is very jolting for a user to experience,

```
. by pid: myprog ... . by pid: sum newvar not sorted r(5);
```

Specifying sortpreserve will prevent this and still allow myprog to sort the data freely. byable() programs that sort the data should specify sortpreserve. It is not necessary to specify sortpreserve if your program does not change the sort order of the data and, in that case, things are a little better if you do not specify sortpreserve.

sortpreserve takes time, although less than you might suspect. sortpreserve does not actually have to re-sort the data at the conclusion of your program—an O(n ln n) operation—it is able to arrange things so that it can reassert the original order of the data in O(n) time, and sortpreserve is, in fact, very quick about it. Nonetheless, there is no reason to waste the time if the data never got out of order.

Concerning sort order, when your byable() program is invoked for the first time, it will be sorted on _byvars but, in subsequent calls (in the case of byable(recall) programs), the sort order will be just as your program leaves it even if you specify sortpreserve. sortpreserve restores the original order after your program has been called for the last time.

613
Remarks and examples

Remarks are presented under the following headings:

- Introduction
- sortpreserve
- The cost of sortpreserve
- How sortpreserve works
- Use of sortpreserve with preserve
- Use of sortpreserve with subroutines that use sortpreserve

Introduction

Properly written programs do one of three things:

1. Report results
2. Add new variables to the dataset
3. Modify the data in memory

However, you do not want to get carried away with the idea. A properly written program might, for instance, report results and yet still have an option to add a new variable to the dataset, but a properly written program would not do all three. The user should be able to obtain reports over and over again by simply retyping the command, and if a command both reports results and modifies the data, that will not be possible.

Properly written programs of the first two types should also not change the sort order of the data. If the data are sorted on mpg and foreign before the command is given, and all the command does is report results, the data should still be sorted on mpg and foreign at the conclusion of the command. Yet the command might find it necessary to sort the data to obtain the results it calculates.

This entry deals with how to easily satisfy both needs.

sortpreserve

You may include sort commands inside your programs and leave the user’s data in the original order when your program concludes by specifying the sortpreserve option on the program definition line:

```
program whatever, sortpreserve
```

That is all there is to it. sortpreserve tells Stata when it starts your program to first record the information about how the data are currently sorted and then later use that information to restore the order to what it previously was. Stata will do this no matter how your program ends, whether as you expected, with an error, or because the user pressed the Break key.

The cost of sortpreserve

There is a cost to sortpreserve, so you do not want to specify the option when it is not needed, but the cost is not much. sortpreserve will consume a little computer time in restoring the sort order at the conclusion of your program. Rather than talking about this time in seconds or milliseconds, which can vary according to the computer you use, let’s define our unit of time as the time to execute:

```
. generate long x = _n
```
Pretend that you added that command to your program, just as we have typed it, without using temporary variables. You could then make careful timings of your program to find out just how much extra time your program would take to execute. It would not be much. Let’s call that amount of time one *genlong* unit. Then

- **sortpreserve**, if it has to restore the order because your program has changed it, takes 2 *genlong* units.
- **sortpreserve**, if it does not need to change the order because your program has not changed it yet, takes one-half a *genlong* unit.

The above results are based on empirical timings using 100,000 and 1,000,000 observations.

**How sortpreserve works**

**sortpreserve** works by adding a temporary variable to the dataset before your program starts, and if you are curious about the name of that variable, it is recorded in the macro ‘*sortindex*’. Sometimes you will want to know that name. It is important that the variable ‘*sortindex*’ still exist at the conclusion of your program. If your program concludes with something like

```stata
keep 'id' 'varlist'
```

you must change that line to read

```stata
keep 'id' 'varlist' '_sortindex'
```

If you fail to do that, Stata will report the error message “could not restore sort order because variables were dropped”. Actually, even that little change may be insufficient because the dataset in its original form might have been sorted on something other than ‘id’ and ‘varlist’. What you really need to do is add, early in your program and before you change the sort order,

```stata
local sortvars : sort
```

and then change the `keep` statement to read

```stata
keep 'id' 'varlist' 'sortvars' '_sortindex'
```

This discussion concerns only the use of the `keep` command. Few programs would even include a `keep` statement because we are skirting the edge of what is a properly written program.

**sortpreserve** is intended for use in programs that report results or add new variables to the dataset, not programs that modify the data in memory. Including `keep` at the end of your program really makes it a class 3 program, and then the idea of preserving the sort order makes no sense anyway.

**Use of sortpreserve with preserve**

**sortpreserve** may be used with `preserve` (see [P] preserve for a description of `preserve`). We can imagine a complicated program that re-sorts the data, and then, under certain conditions, discovers it has to do real damage to the data to calculate its results, and so then preserves the data to boot:
program ..., sortpreserve
... sort ... ...
if ... {
preserve ...
}
...
end

The above program will work. When the program ends, Stata will first restore any preserved data and then reestablish the sort of the original dataset.

Use of sortpreserve with subroutines that use sortpreserve

Programs that use sortpreserve may call other programs that use sortpreserve, and this can be a good way to speed up code. Consider a calculation where you need the data first sorted by ‘i’ ‘j’, then by ‘j’ ‘i’, and finally by ‘i’ ‘j’ again. You might code

program ..., sortpreserve
... sort ‘i’ ‘j’ ...
... sort ‘j’ ‘i’ ...
... sort ‘i’ ‘j’ ...
end

but executing

program ..., sortpreserve
... sort ‘i’ ‘j’
mysubcalculation ‘i’ ‘j’ ...
...
end
program mysubcalculation, sortpreserve
args i j ...
sort ‘j’ ‘i’ ...
end

will be faster.

Also see

[P] byable — Make programs byable
[P] program — Define and manipulate programs
There are two ways that a Stata program can interpret what the user types:

1. positionally, meaning first argument, second argument, and so on, or
2. according to a grammar, such as standard Stata syntax.

`args` does the first. The first argument is assigned to `macroname1`, the second to `macroname2`, and so on. In the program, you later refer to the contents of the macros by enclosing their names in single quotes: `‘macroname1’, ‘macroname2’, ...`

```stata
program myprog
    version 15.0
    args varname dof beta
    (the rest of the program would be coded in terms of ‘varname’, ‘dof’, and ‘beta’)
    ...
end
```

`syntax` does the second. You specify the new command’s syntax on the `syntax` command; for instance, you might code

```stata
program myprog
    version 15.0
    syntax varlist [if] [in] [, DOF(integer 50) Beta(real 1.0)]
    (the rest of the program would be coded in terms of ‘varlist’, ‘if’, ‘in’, ‘dof’, and ‘beta’)
    ...
end
```

`syntax` examines what the user typed and attempts to match it to the syntax diagram. If it does not match, an error message is issued and the program is stopped (a nonzero return code is returned). If it does match, the individual components are stored in particular local macros where you can subsequently access them. In the example above, the result would be to define the local macros `‘varlist’, ‘if’, ‘in’, ‘dof’, and ‘beta’.`

For an introduction to Stata programming, see [U] 18 Programming Stata and especially [U] 18.4 Program arguments.

Standard Stata syntax is

```
cmd    [ varlist | namelist | anything ]
    [ if ]
    [ in ]
    [ using filename ]
    [ = exp ]
    [ weight ]
    [ , options ]
```

Each of these building blocks, such as `varlist`, `namelist`, and `if`, is outlined below.
Syntax

Parse Stata syntax positionally

```
args macroname1 [macroname2 [macroname3 ...]]
```

Parse syntax according to a standard syntax grammar

```
syntax description_of_syntax
```

Syntax, continued

The `description_of_syntax` allowed by `syntax` includes

```
description_of_varlist:       type        nothing
  or                      [               
  optionally type          varlist varname newvarlist newvarname 
  then type one of         (varlist_specifiers)
  optionally type          ]

  type
varlist_specifiers are: default=none min=# max=# numeric
                        string str# strL fv ts
                        generate (newvarlist and newvarname only)
```

Examples:

```
syntax varlist ...
syntax [varlist] ...
syntax varlist(min=2) ...
syntax varlist(max=4) ...
syntax varlist(min=2 max=4 numeric) ...
syntax varlist(default=none) ...

syntax newvarlist(max=1) ...

syntax varname ...
syntax [varname] ...
```

If you type nothing, the command does not allow a varlist.

Typing `[` and `]` means that the varlist is optional.

`default=` specifies how the varlist is to be filled in when the varlist is optional and the user does not specify it. The default is to fill it in with all the variables. If `default=none` is specified, it is left empty.

`min=` and `max=` specify the minimum and maximum number of variables that may be specified. Typing `varname` is equivalent to typing `varlist(max=1)`.

`numeric`, `string`, `str#`, and `strL` restrict the specified varlist to consist of entirely numeric, entirely string (meaning `str#` or `strL`), entirely `str#`, or entirely `strL` variables.

`fv` allows the varlist to contain factor variables.

`ts` allows the varlist to contain time-series operators.

`generate` specifies, for `newvarlist` or `newvarname`, that the new variables be created and filled in with missing values.

After the `syntax` command, the resulting varlist is returned in `‘varlist’`. If there are new variables (you coded `newvarname` or `newvarlist`), the macro `‘typlist’` is also defined, containing the storage type of each new variable, listed one after the other.
description of namelist:

- type
  - nothing
  - optionally type
    - [ namelist name
      - (namelist_specifiers)
    ] (if you typed [ at the start)

namelist_specifiers are

- name=name
- id="text"
- local
- min=# (namelist only)
- max=# (namelist only)

Examples:

- syntax namelist ...
- syntax [namelist] ...
- syntax name(id="equation name") ...
- syntax [namelist(id="equation name")]
- syntax namelist(name=eqlist id="equation list") ...
- syntax [name(name=eqname id="equation name")]
- syntax namelist(min=2 max=2) ...

namelist is an alternative to varlist; it relaxes the restriction that the names the user specifies be of variables. name is a shorthand for namelist(max=1).

namelist is for use when you want the command to have the nearly standard syntax of command name followed by a list of names (not necessarily variable names), followed by if, in, options, etc. For instance, perhaps the command is to be followed by a list of variable-label names.

If you type nothing, the command does not allow a namelist. Typing [ and ] means that the namelist is optional.

After the syntax command, the resulting namelist is returned in `namelist` unless name=name is specified, in which case the result is returned in `name`.

id= specifies the name of namelist and is used in error messages. The default is id=namelist. If namelist were required and id= was not specified, and the user typed “mycmd if...” (omitting the namelist), the error message would be “namelist required”. If you specified id="equation name", the error message would be “equation name required”.

name= specifies the name of the local macro to receive the namelist; not specifying the option is equivalent to specifying name=namelist.

local specifies that the names that the user specifies satisfy the naming convention for local macro names. If this option is not specified, standard naming convention is used (names may begin with a letter or underscore, may thereafter also include numbers, and must not be longer than 32 characters). If the user specifies an invalid name, an error message will be issued. If local is specified, specified names are allowed to begin with numbers but may not be longer than 31 characters.
anything is for use when you want the command to have the nearly standard syntax of command name followed by something followed by \texttt{if}, \texttt{in}, \texttt{options}, etc. For instance, perhaps the command is to be followed by an expression or expressions or a list of numbers.

If you type nothing, the command does not allow an “anything”. Typing \texttt{[} and \texttt{]} means the “anything” is optional. After the \texttt{syntax} command, the resulting “anything list” is returned in \texttt{‘anything’} unless \texttt{name=\textit{name}} is specified, in which case the result is returned in \texttt{‘name’}.

\texttt{id=} specifies the name of “anything” and is used only in error messages. For instance, if \texttt{anything} were required and \texttt{id=} was not specified, and the user typed \texttt{\textit{mycmd} if \ldots} (omitting the “anything”), the error message would be “something required”. If you specified \texttt{id=\textit{expression list}}, the error message would be “expression list required”.

\texttt{name=} specifies the name of the local macro to receive the “anything”; not specifying the option is equivalent to specifying \texttt{name=\textit{anything}}.

\texttt{equalok} specifies that \texttt{=} is not to be treated as part of \texttt{=\textit{exp}} in subsequent standard syntax but instead as part of the anything.

\texttt{everything} specifies that \texttt{if}, \texttt{in}, and \texttt{using} are not to be treated as part of standard syntax but instead as part of the anything.

\texttt{varlist}, \texttt{varname}, \texttt{namelist}, \texttt{name}, and \texttt{anything} are alternatives; you may specify at most one.
description_of_in:

```
type    nothing
or
  optionally type [  
in
  optionally type /  ]
```

(if you typed [ at the start)

Examples:
- `syntax ... in ...
- `syntax ... [in] ...
- `syntax ... [in/] ...
- `syntax ... in/

If you type nothing, the command does not allow an in range.

Typing [ and ] means that the in range is optional.

After the `syntax` command, the resulting in range is returned in ‘in’. The macro contains in followed by the range, unless you specified /, in which case the macro contains just the range.

---

description_of_using:

```
type    nothing
or
  optionally type [  
using
  optionally type /  ]
```

(if you typed [ at the start)

Examples:
- `syntax ... using ...
- `syntax ... [using] ...
- `syntax ... [using/] ...
- `syntax ... using/

If you type nothing, the command does not allow using filename.

Typing [ and ] means that the using filename is optional.

After the `syntax` command, the resulting filename is returned in ‘using’. The macro contains using followed by the filename in quotes, unless you specified /, in which case the macro contains just the filename without quotes.

---

description_of_=exp:

```
type    nothing
or
  optionally type [  
=  
  optionally type /  ]
```

(if you typed [ at the start)

Examples:
- `syntax ... =exp ...
- `syntax ... [=exp] ...
- `syntax ... [=/exp] ...
- `syntax ... =/exp ...

If you type nothing, the command does not allow an =exp.

Typing [ and ] means that the =exp is optional.

After the `syntax` command, the resulting expression is returned in ‘exp’. The macro contains =, a space, and the expression, unless you specified /, in which case the macro contains just the expression.
If you type nothing, the command does not allow weights. A command may not allow both a weight and `exp'.

You must type [ and ]; they are not optional. Weights are always optional.

The first weight specified is the default weight type.

After the `syntax' command, the resulting weight and expression are returned in `weight' and `exp'. `weight' contains the weight type or nothing if no weights were specified. `exp' contains `=', a space, and the expression, unless you specified `/', in which case the macro contains just the expression.

description of options:

type nothing

or

type [,

optionally type *

type ]

or

',

optionally type *

optionally type [,

optionally type [

optionally type *

optionally type ]

Examples:

`syntax ... [, MYopt Thisopt]
`syntax ..., MYopt Thisopt
`syntax ..., MYopt [Thisopt]
`syntax ... [, MYopt Thisopt *]`

If you type nothing, the command does not allow options.

The brackets distinguish optional from required options. All options can be optional, all options can be required, or some can be optional and others be required.

After the `syntax' command, options are returned to you in local macros based on the first 31 letters of each option's name. If you also specify '*', any remaining options are collected and placed, one after the other, in `options'. If you do not specify '*', an error is returned if the user specifies any options that you do not list.

`option_descriptors' include the following; they are documented below.

`optionally_on'
`optionally_off'
`optional_integer_value'
`optional_real_value'
`optional_confidence_interval'
`optional_credible_interval'
`optional_numlist'
`optional_varlist'
`optional_namelist'
`optional_string'
`optional_passthru'
option_descriptor optionally_on:

<table>
<thead>
<tr>
<th>type</th>
<th>OPname</th>
<th>(capitalization indicates minimal abbreviation)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>syntax . . . .</td>
<td>replace . . . .</td>
</tr>
<tr>
<td></td>
<td>syntax . . . .</td>
<td>REPLACE . . . .</td>
</tr>
<tr>
<td></td>
<td>syntax . . . .</td>
<td>detail . . . .</td>
</tr>
<tr>
<td></td>
<td>syntax . . . .</td>
<td>Detail . . . .</td>
</tr>
<tr>
<td></td>
<td>syntax . . . .</td>
<td>CONStant . . .</td>
</tr>
</tbody>
</table>

Examples: syntax . . . . replace . . . .
syntax . . . . REPLACE . . . .
syntax . . . . detail . . . .
syntax . . . . Detail . . . .
syntax . . . . CONStant . . .

The result of the option is returned in a macro name formed by the first 31 letters of the option's name. Thus option replace is returned in local macro ‘replace’; option detail, in local macro ‘detail’; and option constant, in local macro ‘constant’.

The macro contains nothing if not specified, or else it contains the macro’s name, fully spelled out.

Warning: Be careful if the first two letters of the option’s name are no, such as the option called notice. You must capitalize at least the N in such cases.

option_descriptor optionally_off:

<table>
<thead>
<tr>
<th>type</th>
<th>OPname</th>
<th>(capitalization indicates minimal abbreviation)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>syntax . . . . noreplace . . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . noREPLACE . . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . nodetail . . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . noDetail . . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . noCONStant . . .</td>
<td></td>
</tr>
</tbody>
</table>

Examples: syntax . . . . noreplace . . . .
syntax . . . . noREPLACE . . . .
syntax . . . . nodetail . . . .
syntax . . . . noDetail . . . .
syntax . . . . noCONStant . . .

The result of the option is returned in a macro name formed by the first 31 letters of the option’s name, excluding the no. Thus option noreplace is returned in local macro ‘replace’; option nodetail, in local macro ‘detail’; and option noconstant, in local macro ‘constant’.

The macro contains nothing if not specified, or else it contains the macro’s name, fully spelled out, with a no prefixed. That is, in the noREPLACE example above, macro ‘replace’ contains nothing, or it contains noreplace.

option_descriptor optional_integer_value:

<table>
<thead>
<tr>
<th>type</th>
<th>OPname</th>
<th>(capitalization indicates minimal abbreviation)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>syntax . . . . Count(integer 3) . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . Sequence(integer 1) . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . dof(integer -1) . . .</td>
<td></td>
</tr>
</tbody>
</table>

Examples: syntax . . . . Count(integer 3) . . .
syntax . . . . Sequence(integer 1) . . .
syntax . . . . dof(integer -1) . . .

The result of the option is returned in a macro name formed by the first 31 letters of the option’s name.

The macro contains the integer specified by the user, or else it contains the default value.

option_descriptor optional_real_value:

<table>
<thead>
<tr>
<th>type</th>
<th>OPname</th>
<th>(capitalization indicates minimal abbreviation)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>syntax . . . . Mean(real 2.5) . . .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>syntax . . . . SD(real -1) . . .</td>
<td></td>
</tr>
</tbody>
</table>

Examples: syntax . . . . Mean(real 2.5) . . .
syntax . . . . SD(real -1) . . .

The result of the option is returned in a macro name formed by the first 31 letters of the option’s name.

The macro contains the real number specified by the user, or else it contains the default value.
**option_descriptor optional_confidence_interval:**

```plaintext
type OPname          (capitalization indicates minimal abbreviation)
type (cilevel)

Example:         syntax ..., ... Level(cilevel) ...
```

The result of the option is returned in a macro name formed by the first 31 letters of the option’s name.

If the user specifies a valid level for a confidence interval, the macro contains that value; see [R] level. If the user specifies an invalid level, an error message is issued, and the return code is 198.

If the user does not type this option, the macro contains the default level obtained from `c(level)`.

**option_descriptor optional_credible_interval:**

```plaintext
type OPname          (capitalization indicates minimal abbreviation)
type (crlevel)

Example:         syntax ..., ... CLEVel(crlevel) ...
```

The result of the option is returned in a macro name formed by the first 31 letters of the option’s name.

If the user specifies a valid level for a credible interval, the macro contains that value; see [BAYES] set clevel. If the user specifies an invalid level, an error message is issued, and the return code is 198.

If the user does not type this option, the macro contains the default level obtained from `c(clevel)`.

**option_descriptor optional_numlist:**

```plaintext
type OPname          (capitalization indicates minimal abbreviation)
type (numlist)
type ascending or descending or nothing
optionally type integer
optionally type missingokay
optionally type min=#
optionally type max=#
optionally type ># or >=# or nothing
optionally type <# or <=# or nothing
optionally type sort
type)

Examples:     syntax ..., ... VALues(numlist) ...
syntax ..., ... VALues(numlist max=10 sort) ...
syntax ..., ... TIME(numlist >0) ...
syntax ..., ... FREQuency(numlist >0 integer) ...
syntax ..., ... OCCur(numlist missingokay >=0 <1e+9) ...
```

The result of the option is returned in a macro name formed by the first 31 letters of the option’s name.

The macro contains the values specified by the user, but listed out, one after the other. For instance, the user might specify `time(1(1)4,10)` so that the local macro ‘time’ would contain “1 2 3 4 10”.

`min` and `max` specify the minimum and maximum number of elements that may be in the list.

`<`, `<=`, `>`, and `>=` specify the range of elements allowed in the list.

`integer` indicates that the user may specify integer values only.

`missingokay` indicates that the user may specify missing values as list elements.

`ascending` specifies that the user must give the list in ascending order without repeated values. `descending` specifies that the user must give the list in descending order without repeated values.

`sort` specifies that the list be sorted before being returned. Distinguish this from modifier `ascending`, which states that the user must type the list in ascending order. `sort` says that the user may type the list in any order but it is to be returned in ascending order. `ascending` states that the list may have no repeated elements. `sort` places no such restriction on the list.
option_descriptor optional_varlist:

<table>
<thead>
<tr>
<th>Type</th>
<th>OPname</th>
<th>(capitalization indicates minimal abbreviation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>optionally type</td>
<td>varlist or varname</td>
<td>numeric or string</td>
</tr>
<tr>
<td>optionally type</td>
<td>min=#</td>
<td></td>
</tr>
<tr>
<td>optionally type</td>
<td>max=#</td>
<td></td>
</tr>
<tr>
<td>optionally type</td>
<td>fv</td>
<td></td>
</tr>
<tr>
<td>optionally type</td>
<td>ts</td>
<td></td>
</tr>
</tbody>
</table>

Examples:

syntax ..., ... ROW(varname) ...  
syntax ..., ... BY(varlist) ...  
syntax ..., ... Counts(varname numeric) ...  
syntax ..., ... Titlevar(varname string) ...  
syntax ..., ... Sizes(varlist numeric min=2 max=10) ...

The result of the option is returned in a macro name formed by the first 31 letters of the option's name. The macro contains the names specified by the user, listed one after the other.

min indicates the minimum number of variables to be specified if the option is given. min=1 is the default.

max indicates the maximum number of variables that may be specified if the option is given. max=800 is the default for varlist (you may set it to be larger), and max=1 is the default for varname.

numeric specifies that the variable list must consist entirely of numeric variables. string specifies that the variable list must consist entirely of string variables, meaning str# or strL. str# and strL specify that the variable list must consist entirely of str# or strL variables, respectively.

fv specifies that the variable list may contain factor variables.

ts specifies that the variable list may contain time-series operators.

option_descriptor optional_namelist:

<table>
<thead>
<tr>
<th>Type</th>
<th>OPname</th>
<th>(capitalization indicates minimal abbreviation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>optionally type</td>
<td>namelist or name</td>
<td></td>
</tr>
<tr>
<td>optionally type</td>
<td>min=#</td>
<td></td>
</tr>
<tr>
<td>optionally type</td>
<td>max=#</td>
<td></td>
</tr>
<tr>
<td>optionally type</td>
<td>local</td>
<td></td>
</tr>
</tbody>
</table>

Examples:

syntax ..., ... GENerate(name) ...  
syntax ..., ... MATrix(name) ...  
syntax ..., ... REsults(namelist min=2 max=10) ...

The result of the option is returned in a macro name formed by the first 31 letters of the option's name. The macro contains the variables specified by the user, listed one after the other.

Do not confuse namelist with varlist. varlist is the appropriate way to specify an option that is to receive the names of existing variables. namelist is the appropriate way to collect names of other things—such as matrices—and namelist is sometimes used to obtain the name of a new variable to be created. It is then your responsibility to verify that the name specified does not already exist as a Stata variable.

min indicates the minimum number of names to be specified if the option is given. min=1 is the default.

max indicates the maximum number of names that may be specified if the option is given. The default is max=1 for name. For namelist, the default is the maximum number of variables allowed in Stata.

local specifies that the names the user specifies are to satisfy the naming convention for local macro names.
The result of the option is returned in a macro name formed by the first 31 letters of the option’s name. The macro contains the string specified by the user, or else it contains nothing.

The macro contains the full option—unabbreviated option name, parentheses, and argument—as specified by the user, or else it contains nothing. For instance, if the user typed `ti("My Title")`, the macro would contain `title("My Title")`.

Remarks and examples

Remarks are presented under the following headings:

Introduction
The `args` command
The `syntax` command

Introduction

Stata is programmable, making it possible to implement new commands. This is done with the `program` definition statement:

```stata
program newcmd
    ...
end
```

The first duty of the program is to parse the arguments that it receives.

Programmers use positional argument passing for subroutines and for some new commands with exceedingly simple syntax. It is so easy to program. If program `myprog` is to receive a variable name (call it `varname`) and two numeric arguments (call them `dof` and `beta`), all they need to code is

```stata
program myprog
    args varname dof beta
    (the rest of the program would be coded in terms of `varname', `dof', and `beta')
    ...
end
```
The disadvantage of this is from the caller’s side, because problems would occur if the caller got the arguments in the wrong order or did not spell out the variable name, etc.

The alternative is to use standard Stata syntax. *syntax* makes it easy to make new command *myprog* have the syntax

```
myprog varname [, dof(#) beta(#) ]
```

and even to have defaults for *dof()* and *beta()*:

```
program myprog
    syntax varlist(max=1) [, Dof(integer 50) Beta(real 1.0)]
    (the rest of the program would be coded in terms of ‘varlist’, ‘dof’, and ‘beta’)
    ...
end
```

**The args command**

`args` splits what the user typed into words and places the first word in the first macro specified; the second, in the second macro specified; and so on:

```
program myprog
    args arg1 arg2 arg3 ...
    do computations using local macros ‘arg1’, ‘arg2’, ‘arg3’, ...
end
```

`args` never produces an error. If the user specified more arguments than the macros specified, the extra arguments are ignored. If the user specified fewer arguments, the extra macros are set to contain "".

A better version of this program would read

```
program myprog
    version 15.0 ← new
    args arg1 arg2 arg3 ...
    do computations using local macros ‘arg1’, ‘arg2’, ‘arg3’, ...
end
```

Placing `version 15.0` as the first line of the program ensures that the command will continue to work with future versions of Stata; see [U] 16.1.1 Version and [P] version. We will include the version line from now on.

**Example 1**

The following command displays the three arguments it receives:

```
. program argdisp
1.     version 15.0
2.     args first second third
3.     display "1st argument = ‘first’"
4.     display "2nd argument = ‘second’"
5.     display "3rd argument = ‘third’"
6.     end
. argdisp cat dog mouse
1st argument = cat
2nd argument = dog
3rd argument = mouse
. argdisp 3.456 2+5-12 X*3+cat
1st argument = 3.456
2nd argument = 2+5-12
3rd argument = X*3+cat
```
Arguments are defined by the spaces that separate them. “X*3+cat” is one argument, but if we had typed “X*3 + cat”, that would have been three arguments.

If the user specifies fewer arguments than expected by `args`, the additional local macros are set as empty. By the same token, if the user specifies too many, they are ignored:

```
   . argdisp cat dog
   1st argument = cat
   2nd argument = dog
   3rd argument =
   . argdisp cat dog mouse cow
   1st argument = cat
   2nd argument = dog
   3rd argument = mouse
```

Technical note

When a program is invoked, exactly what the user typed is stored in the macro ‘0’. Also the first word of that is stored in ‘1’; the second, in ‘2’; and so on. `args` merely copies the ‘1’, ‘2’, … macros. Coding

```
   args arg1 arg2 arg3
```

is no different from coding

```
   local arg1 `'1'
   local arg2 `'2'
   local arg3 `'3'
```

The syntax command

`syntax` is easy to use. `syntax` parses standard Stata syntax, which is

```
   command varlist if exp in range [weight] using filename, options
```

Actually, standard syntax is a little more complicated than that because you can substitute other things for `varlist`. In any case, the basic idea is that you code a `syntax` command describing which parts of standard Stata syntax you expect to see. For instance, you might code

```
   syntax varlist if in, title(string) adjust(real 1)
```

or

```
   syntax [varlist] [if] [in] [, title(string) adjust(real 1)]
```

In the first example, you are saying that everything is required. In the second, everything is optional. You can make some elements required and others optional:

```
   syntax varlist [if] [in], adjust(real) [title(string)]
```

or

```
   syntax varlist [if] [in] [, adjust(real 1) title(string)]
```

or many other possibilities. Square brackets denote that something is optional. Put them around what you wish.
You code what you expect the user to type. `syntax` then compares that with what the user actually did type, and, if there is a mismatch, `syntax` issues an error message. Otherwise, `syntax` processes what the user typed and stores the pieces, split into categories, in macros. These macros are named the same as the syntactical piece:

The varlist specified will go into ‘varlist’
The `if` exp will go into ‘if’
The `in` range will go into ‘in’
The `adjust()` option’s contents will go into ‘adjust’
The `title()` option’s contents will go into ‘title’

Go back to the section *Syntax, continued;* where each element is stored is explicitly stated. When a piece is not specified by the user, the corresponding macro is cleared.

### Example 2

The following program simply displays the pieces:

```stata
. program myprog
  1. version 15.0
  2. syntax varlist [if] [in] [, adjust(real 1) title(string)]
  3. display "varlist contains |'varlist'|"
  4. display " if contains |'if'|"
  5. display " in contains |'in'|"
  6. display " adjust contains |'adjust'|"
  7. display " title contains |'title'|"
  8. end

. myprog
   varlist required
r(100);
```

Well, that should not surprise us; we said that the varlist was required in the `syntax` command, so when we tried `myprog` without explicitly specifying a varlist, Stata complained.

```stata
. myprog mpg weight
   varlist contains |mpg weight|
       if contains ||
       in contains ||
       adjust contains |1|
       title contains ||

. myprog mpg weight if foreign
   varlist contains |mpg weight|
       if contains |if foreign|
       in contains ||
       adjust contains |1|
       title contains ||

. myprog mpg weight in 1/20
   varlist contains |mpg weight|
       if contains ||
       in contains |in 1/20|
       adjust contains |1|
       title contains ||

. myprog mpg weight in 1/20 if foreign
   varlist contains |mpg weight|
       if contains |if foreign|
       in contains |in 1/20|
       adjust contains |1|
       title contains ||
```
That is all there is to it.

Example 3

After completing the last example, it would not be difficult to actually make myprog do something. For lack of a better example, we will change myprog to display the mean of each variable, with said mean multiplied by adjust():

```stata
program myprog
    version 15.0
    syntax varlist [if] [in] [, adjust(real 1) title(string)]
    display if "title" != "" {
        display "'title':"
    }
    foreach var of local varlist {
        quietly summarize 'var' 'if' 'in'
        display %9s "'var':" %9.0g r(mean)*'adjust'
    }
end
```

. myprog mpg weight
    mpg 21.2973
    weight 3019.459

. myprog mpg weight if foreign==1
    mpg 24.77273
    weight 2315.909

. myprog mpg weight if foreign==1, title("My title")
    My title:
    mpg 24.77273
    weight 2315.909

. myprog mpg weight if foreign==1, title("My title") adjust(2)
    My title:
    mpg 49.54545
    weight 4631.818

Technical note

myprog is hardly deserving of any further work, given what little it does, but let’s illustrate two ideas that use it.
First, we will learn about the `marksample` command; see [P] `mark`. A common mistake is to use one sample in one part of the program and a different sample in another part. The solution is to create at the outset a variable that contains 1 if the observation is to be used and 0 otherwise. `marksample` will do this correctly because `marksample` knows what `syntax` has just parsed:

```stata
program myprog
    version 15.0
    syntax varlist [if] [in] [, adjust(real 1) title(string)]
    marksample touse ← new
display
    if "'title'" != "" {
        display "title:"
    }
    foreach var of local varlist {
        quietly summarize 'var' if 'touse' ← changed
display %9s 'var' " " %9.0g r(mean)*'adjust'
    }
end
```

Second, we will modify our program so that what is done with each variable is done by a subroutine. Pretend here that we are doing something more involved than calculating and displaying a mean.

We want to make this modification to show you the proper use of the `args` command. Passing arguments by position to subroutines is convenient, and there is no chance of error due to arguments being out of order (assuming that we wrote our program properly):

```stata
program myprog
    version 15.0
    syntax varlist [if] [in] [, adjust(real 1) title(string)]
    marksample touse
display
    if "'title'" != "" {
        display "title:"
    }
    foreach var of local varlist {
        doavar 'touse' 'var' 'adjust'
    }
end
program doavar
    version 15.0
    args touse name value
    quietly summarize 'name' if 'touse'
display %9s 'name' " " %9.0g r(mean)*'value'
end
```

[U] 16.1.1 Version
[U] 18 Programming Stata
[U] 18.3.1 Local macros
[U] 18.3.5 Double quotes
**sysdir** — Query and set system directories

### Description

`sysdir` lists Stata’s system directories.

`sysdir set` changes the path to Stata’s system directories.

`personal` displays the path of the PERSONAL directory. `personal dir` gives a directory listing of the files contained in the PERSONAL directory.

`adopath` displays the ado-file path stored in the global macro `S_ADO`.

`adopath +` adds a new directory or moves an existing directory to the end of the search path stored in the global macro `S_ADO`.

`adopath ++` adds a new directory or moves an existing directory to the beginning of the search path stored in the global macro `S_ADO`.

`adopath -` removes a directory from the search path stored in the global macro `S_ADO`.

`set adosize` sets the maximum amount of memory in kilobytes that automatically loaded do-files may consume. The default is `set adosize 1000`. To view the current setting, type `display c(adosize)`.

These commands have to do with technical aspects of Stata’s implementation. Except for `sysdir list`, you should never have to use them.

### Syntax

**List Stata’s system directories**

```
sysdir [list]
```

**Reset Stata’s system directories**

```
sysdir set codeword ["]path["]
```

**Display path of PERSONAL directory and list files in it**

```
personal [dir]
```

**Display ado-file path**

```
adopath
```

**Add directory to end of ado-path**

```
adopath + path_or_codeword
```
Add directory to beginning of ado-path

\texttt{adopath ++ path\_or\_codeword}

Remove directory from ado-path

\texttt{adopath - \{path\_or\_codeword | \#\}}

Set maximum memory ado-files may consume

\texttt{set adosize \# \{, permanently \} 10 \leq \# \leq 10000}

where \texttt{path} must be enclosed in double quotes if it contains blanks or other special characters and \texttt{codeword} is \{ \texttt{STATA | BASE | SITE | PLUS | PERSONAL | OLDPLACE} \}.

Option

\texttt{permanently} specifies that, in addition to making the change right now, the \texttt{adosize} setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

Remarks are presented under the following headings:

\texttt{Introduction}
\texttt{sysdir}
\texttt{adopath}
\texttt{set adosize}

Introduction

In various parts of the Stata documentation, you will read that “Stata searches along the ado-path” for such-and-such. When we say that, what we really mean is “Stata searches along the path stored in the global macro \$S\_ADO”. Equivalently, we could say “searches along the path stored in \texttt{c(adopath)}” because \texttt{c(adopath)} = \$S\_ADO. These are just two different ways of saying the same thing. If you wanted to change the path, however, you would change the \$S\_ADO because there is no way to change \texttt{c(adopath)}.

Do not, however, directly change \$S\_ADO. Even if you have good reason to change it, you will find it easier to change it via the \texttt{adopath} command.

If you were to look inside \$S\_ADO (and we will), you would discover that it does not actually contain directory names—although it could—but contains codewords that stand for directory names. The \texttt{sysdir} command will show you the meaning of the codewords and allow you to change them.
sysdir

Stata expects to find various parts of itself in various directories (folders). Rather than describing these directories as C:\Program Files\Stata15\ado\base or /usr/local/stata/ado, these places are referred to by codewords. Here are the definitions of the codewords on a particular Windows computer:

```
  . sysdir
    STATA: C:\Program Files\Stata15\n    BASE: C:\Program Files\Stata15\ado\base\n    SITE: C:\Program Files\Stata15\ado\site\n    PLUS: C:\ado\plus\n    PERSONAL: C:\ado\personal\n    OLDPLACE: C:\ado\n```

Even if you use Stata for Windows, when you type `sysdir`, you might see different directories listed.

The `sysdir` command allows you to obtain the correspondence between codeword and actual directory, and it allows you to change the mapping. Each directory serves a particular purpose:

- **STATA** refers to the directory where the Stata executable is to be found.
- **BASE** is where the original official ado-files that were shipped with Stata and any updated official ado-files that have been made available since then are installed.
- **SITE** is relevant only on networked computers. It is where administrators may place ado-files for sitewide use on networked computers. No Stata command writes to this directory, but administrators may move files into the directory or obtain ado-files by using `net` and choose to install them into this directory; see [R] `net`.
- **PLUS** is relevant on all systems. It is where ado-files written by other people that you obtain using the `net` command are installed; by default, `net` installs files to this directory; see [R] `net`.
- **PERSONAL** is where you are to copy ado-files that you write and that you wish to use regardless of your current directory when you use Stata. (The alternative is to put ado-files in your current directory, and then they will be available only when you are in that directory.)
- **OLDPLACE** is included for backward compatibility. Stata 5 users used to put ado-files here, both the personal ones and the ones written by others. Nowadays, they are supposed to put their personal files in PERSONAL and the ones written by others in PLUS.

Do not change the definitions of **BASE**, You may want to change the definitions of **SITE**, PERSONAL, PLUS, or especially **OLDPLACE**. For instance, if you want to change the definition of **OLDPLACE** to `d:\ado`, type

```
  . sysdir set OLDPLACE "d:\ado"
```

Resetting a system directory affects only the current session; the next time you enter Stata, the system directories will be set back to being as they originally were. If you want to reset a system directory permanently, place the `sysdir set` command in your `profile.do`; see [GSW] B.3 Executing commands every time Stata is started, [GSM] B.1 Executing commands every time Stata is started, or [GSU] B.1 Executing commands every time Stata is started.
adopath

adopath displays and resets the contents of the global macro $S_ADO$, the path over which Stata searches for ado-files. The default search path is

```
. adopath
[1] (BASE)   "C:\Program Files\Stata15\ado\base"
[2] (SITE)   "C:\Program Files\Stata15\ado\site"
[3]        
[4] (PERSONAL) "C:\ado\personal"
[5] (PLUS)   "C:\ado\plus"
[6] (OLDPLACE) "C:\ado"
[7] "C:\myprogs"
```

Focus on the codewords on the left. adopath mentions the actual directories, but if you changed the meaning of a codeword by using sysdir, that change would affect adopath.

The above states that, when Stata looks for an ado-file, first it looks in BASE. If the ado-file is found, then that copy is used. If it is not found, then Stata next looks in SITE, and if it is found there, then that copy is used. And so the process continues. At the fourth step, Stata looks in the current directory (for which there is no codeword).

adopath merely presents the information in $S_ADO$ in a more readable form:

```
. display "$S_ADO"
BASE;SITE;.;PERSONAL;PLUS;OLDPLACE
```

adopath can also change the contents of the path. In general, you should not do this unless you are sure of what you are doing because many features of Stata will stop working if you change the path incorrectly. At worst, however, you might have to exit and reenter Stata, so you cannot do any permanent damage. Moreover, it is safe to add to the end of the path.

The path may include actual directory names, such as $C:\myprogs$, or codewords, such as PERSONAL, PLUS, and OLDPLACE. To add $C:\myprogs$ to the end of the path, type

```
. adopath + C:\myprogs
```

If later you want to remove $C:\myprogs$ from the ado-path, you could type `adopath - C:\myprogs`, but easier is

```
. adopath - 8
```

When followed by a number, `adopath -` removes that element from the path. If you cannot remember what the numbers are, you can first type `adopath` without arguments.

Technical note

`adopath ++ path` works like `adopath + path`, except that it adds to the beginning rather than to the end of the path. Our recommendation is that you not do this. When looking for `name.ado`, Stata
loads the first file it encounters as it searches along the path. If you did not like our implementation of the command ci, for instance, even if you wrote your own and stored it in ci.ado, Stata would continue to use the one in the Stata directory because that is the directory listed earlier in the path. To force Stata to use yours rather than ours, you would have to put at the front of the path the name of the directory where your ado-file resides.

You should not, however, name any of your ado-files the same as we have named ours. If you add to the front of the path, you assume exclusive responsibility for the Stata commands working as documented in this manual.

set adosize

Stata keeps track of the ado-commands you use and discards from memory commands that have not been used recently. Stata discards old commands to keep the amount of memory consumed by such commands less than adosize. The default value of 1,000 means the total amount of memory consumed by ado-commands is not to exceed 1,000 KB. When an ado-command has been discarded, Stata will have to reload the command the next time you use it.

You can increase adosize. Typing set adosize 1550 would allow up to 1,550 KB to be allocated to ado-commands. This would improve performance slightly if you happened to use one of the not-recently-used commands, but at the cost of some memory no longer being available for your dataset. In practice, there is little reason to increase adosize.

adosize must be between 10 and 10,000.

[U] 17.5 Where does Stata look for ado-files?
**Description**

`tabdisp` displays data in a table. `tabdisp` calculates no statistics and is intended for use by programmers.

For the corresponding command that calculates statistics and displays them in a table, see [R] table. Although `tabdisp` is intended for programming applications, it can be used interactively for listing data.

**Syntax**

\[\texttt{tabdisp rowvar [colvar [supercolvar]]} [if] [in], \texttt{cellvar(varnames)} \]

[by(superrowvars) format(%fmt) center left concise missing totals dotz cellwidth(#) csepwidth(#) scsepwidth(#) stubwidth(#)]

`by` is allowed; see [D] by.

`rowvar`, `colvar`, and `supercolvar` may be numeric or string variables. Rows, columns, supercolumns, and superrows are thus defined as

\[
\begin{array}{c|c}
\hline
\text{row 1} & . \\
\text{row 2} & . \\
\hline
\end{array}
\quad
\begin{array}{c|c|c}
\hline
\text{supercol 1} & \text{col 1} & \text{col 2} \\
\hline
\text{row 1} & . & . \\
\text{row 2} & . & . \\
\hline
\end{array}
\quad
\begin{array}{c|c|c}
\hline
\text{supercol 1} & \text{col 1} & \text{col 2} \\
\hline
\text{supercol 2} & \text{col 1} & \text{col 2} \\
\hline
\text{superrow 1:} & \text{row 1} & . & . & . \\
\text{superrow 2:} & \text{row 1} & . & . & . \\
\text{row 1} & . & . & . \\
\text{row 2} & . & . & . \\
\hline
\end{array}
\]

638
Options

cellvar(varnames) is required; it specifies the numeric or string variables containing the values to be displayed in the table’s cells. Up to five variable names may be specified.

by(superrowvars) specifies numeric or string variables to be treated as superrows. Up to four variables may be specified.

format(%fmt) specifies the display format for presenting numbers in the table’s cells. format(%9.0g) is the default; format(%9.2f) is a popular alternative. The width of the format you specify does not matter, except that %fmt must be valid. The width of the cells is chosen by tabdisp to be what it thinks looks best. The cellwidth() option allows you to override tabdisp’s choice.

center specifies that results be centered in the table’s cells. The default is to right-align results. For centering to work well, you typically need to specify a display format as well. center format(%9.2f) is popular.

left specifies that column labels be left-aligned. The default is to right-align column labels to distinguish them from supercolumn labels, which are left-aligned. If you specify left, both column and supercolumn labels are left-aligned.

concise specifies that rows with all missing entries not be displayed.

missing specifies that, in cells containing missing values, the missing value (. , .a , .b , ..., or .z) be displayed. The default is that cells with missing values are left blank.

totals specifies that observations where rowvar, colvar, supercolvar, or superrowvars contain the system missing value (.) be interpreted as containing the corresponding totals of cellvar(), and that the table be labeled accordingly. If the dotz option is also specified, observations where the stub variables contain .z will be thus interpreted.

dotz specifies that the roles of missing values . and .z be interchanged in labeling the stubs of the table. By default, if any of rowvar, colvar, supercolvar, and superrowvars contains missing (., .a, .b, ., or .z), then “.” is placed last in the ordering. dotz specifies that .z be placed last. Also, if option totals is specified, .z values rather than “.” values will be labeled “Total”.

cellwidth(#) specifies the width of the cell in units of digit widths; 10 means the space occupied by 10 digits, which is 0123456789. The default cellwidth() is not a fixed number but rather a number chosen by tabdisp to spread the table out while presenting a reasonable number of columns across the page.

csepwidth(#) specifies the separation between columns in units of digit widths. The default is not a fixed number but rather a number chosen by tabdisp according to what it thinks looks best.

scsepwidth(#) specifies the separation between supercolumns in units of digit widths. The default is not a fixed number but rather a number chosen by tabdisp according to what it thinks looks best.

stubwidth(#) specifies the width, in units of digit widths, to be allocated to the left stub of the table. The default is not a fixed number but rather a number chosen by tabdisp according to what it thinks looks best.

Remarks and examples

Remarks are presented under the following headings:

Limits
Introduction
Treatment of string variables
Treatment of missing values
Limits

Up to four variables may be specified in the `by()` option, so with the three row, column, and supercolumn variables, seven-way tables may be displayed.

Up to five variables may be displayed in each cell of the table.

The sum of the number of rows, columns, supercolumns, and superrows is called the number of margins. A table may contain up to 3,000 margins. Thus a one-way table may contain 3,000 rows. A two-way table could contain 2,998 rows and 2 columns, 2,997 rows and 3 columns, ..., 1,500 rows and 1,500 columns, ..., or 2 rows and 2,998 columns. A three-way table is similarly limited by the sum of the number of rows, columns, and supercolumns. An \( r \times c \times d \) table is feasible if \( r + c + d \leq 3,000 \). The limit is set in terms of the sum of the rows, columns, supercolumns, and superrows—not, as you might expect, their product.

Introduction

If you have not read [R] table, please do so. `tabdisp` is what `table` uses to display the tables. `tabdisp` calculates nothing. `tabdisp` instead displays the data in memory. In this, think of `tabdisp` as an alternative to `list`. Consider the following little dataset:

```
. use http://www.stata-press.com/data/r15/tabdxmpl1
. list
    +----+----+----+
    | a  | b  | c  |
    +----+----+----+
    | 0  | 1  | 15 |
    | 0  | 2  | 26 |
    | 0  | 3  | 11 |
    | 1  | 1  | 14 |
    | 1  | 2  | 12 |
    | 1  | 3  |  7|
    +----+----+----+
```

We can use `tabdisp` to list it:

```
. tabdisp a b, cell(c)
```

```
 a | b
---+---+---+
 0 | 15| 26| 11|
 1 | 14| 12|  7|
---+---+---+
```

`tabdisp` is merely an alternative way to list the data. It is when the data in memory are statistics by category that `tabdisp` becomes really useful. `table` provides one prepackaging of that idea.

Unlike `list`, `tabdisp` is unaffected by the order of the data. Here are the same data in a different order:
. use http://www.stata-press.com/data/r15/tabdxmpl2
. list

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>14</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>15</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>26</td>
</tr>
</tbody>
</table>

and yet the output of `tabdisp` is unaffected.

. tabdisp a b, cell(c)

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>14</td>
</tr>
</tbody>
</table>

Nor does `tabdisp` care if one of the cells is missing in the data.

. drop in 6
        (1 observation deleted)
. tabdisp a b, cell(c)

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>14</td>
</tr>
</tbody>
</table>

On the other hand, `tabdisp` assumes that each value combination of the row, column, superrow, and supercolumn variables occurs only once. If that is not so, `tabdisp` displays the earliest occurring value:

. input
    a   b   c
  6. 0   1   99
  7. end
. list

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>14</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>15</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>99</td>
</tr>
</tbody>
</table>
Thus our previous claim that `tabdisp` was unaffected by sort order has this one exception.

Finally, `tabdisp` uses variable and value labels when they are defined:

```
. label var a "Sex"
. label define sex 0 male 1 female
. label values a sex
. label var b "Treatment Group"
. label def tg 1 "controls" 2 "low dose" 3 "high dose"
. label values b tg
. tabdisp a b, cell(c)
```

<table>
<thead>
<tr>
<th>Sex</th>
<th>Treatment Group</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>controls</td>
<td>low dose</td>
<td>high dose</td>
<td></td>
</tr>
<tr>
<td>male</td>
<td>15</td>
<td>11</td>
<td></td>
<td></td>
</tr>
<tr>
<td>female</td>
<td>14</td>
<td>12</td>
<td>7</td>
<td></td>
</tr>
</tbody>
</table>

There are two things you can do with `tabdisp`. 
You can use it to list data, but be certain that you have a unique identifier. In the automobile dataset, the variable `make` is unique:

```
use http://www.stata-press.com/data/r15/auto2, clear
(1978 Automobile Data)
.list make mpg weight displa-t rep78
```

<table>
<thead>
<tr>
<th>make</th>
<th>mpg</th>
<th>weight</th>
<th>displa-t</th>
<th>rep78</th>
</tr>
</thead>
<tbody>
<tr>

Mostly, however, `tabdisp` is intended for use when you have a dataset of statistics that you want to display:

```
. collapse (mean) mpg, by(foreign rep78)
. list

<table>
<thead>
<tr>
<th>rep78</th>
<th>foreign</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poor</td>
<td>Domestic</td>
<td>21</td>
</tr>
<tr>
<td>Fair</td>
<td>Domestic</td>
<td>19.125</td>
</tr>
<tr>
<td>Average</td>
<td>Domestic</td>
<td>19</td>
</tr>
<tr>
<td>Good</td>
<td>Domestic</td>
<td>18.4444</td>
</tr>
<tr>
<td>Excellent</td>
<td>Domestic</td>
<td>32</td>
</tr>
<tr>
<td>.</td>
<td>Domestic</td>
<td>23.25</td>
</tr>
<tr>
<td>Average</td>
<td>Foreign</td>
<td>23.3333</td>
</tr>
<tr>

<td>19.00</td>
<td>18.4444</td>
<td>32.00</td>
</tr>
<tr>
<td>Foreign</td>
<td>23.3333</td>
<td>24.8889</td>
<td>26.3333</td>
<td>14.00</td>
<td></td>
</tr>
</tbody>
</table>

. drop if rep78==.
(2 observations deleted)
. `tabdisp foreign rep78, cell(mpg) format(%9.2f) center`

<table>
<thead>
<tr>
<th>Car type</th>
<th>Poor</th>
<th>Fair</th>
<th>Average</th>
<th>Good</th>
<th>Excellent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>21.00</td>
<td>19.125</td>
<td>19.00</td>
<td>18.4444</td>
<td>32.00</td>
</tr>
<tr>
<td>Foreign</td>
<td>23.3333</td>
<td>24.89</td>
<td>26.3333</td>
<td>14.00</td>
<td></td>
</tr>
</tbody>
</table>

### Treatment of string variables

The variables specifying the rows, columns, supercolumns, and superrows may be numeric or string. Also, the variables specified for inclusion in the table may be numeric or string. In the example below, all variables are strings, including `reaction`:

```
. use http://www.stata-press.com/data/r15/tabdxmpl3, clear
. tabdisp agecat sex party, c(reaction) center

<table>
<thead>
<tr>
<th>Party Affiliation and Sex</th>
<th>Democrat</th>
<th>Republican</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>Male</td>
<td>Female</td>
</tr>
<tr>
<td>Old Young</td>
<td>Favor</td>
<td>Favor</td>
</tr>
<tr>
<td></td>
<td>Strongly Favor</td>
<td>Indifferent</td>
</tr>
</tbody>
</table>
```

. use http://www.stata-press.com/data/r15/tabdxmpl3, clear
. tabdisp agecat sex party, c(reaction) center

<table>
<thead>
<tr>
<th>Party Affiliation and Sex</th>
<th>Democrat</th>
<th>Republican</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>Male</td>
<td>Female</td>
</tr>
<tr>
<td>Old Young</td>
<td>Favor</td>
<td>Favor</td>
</tr>
<tr>
<td></td>
<td>Strongly Favor</td>
<td>Indifferent</td>
</tr>
</tbody>
</table>
Treatment of missing values

The `cellvar()` variables specified for inclusion in the table may contain missing values, and whether the variable contains a missing value or the observation is missing altogether makes no difference:

```
. use http://www.stata-press.com/data/r15/tabdxmpl4
. list

<table>
<thead>
<tr>
<th>sex</th>
<th>response</th>
<th>pop</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>12</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>0</td>
<td>2</td>
<td>.a</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>11</td>
</tr>
</tbody>
</table>
```

```
. tabdisp sex response, cell(pop)
```

<table>
<thead>
<tr>
<th>Sex</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12 20</td>
</tr>
<tr>
<td>1</td>
<td>15 11</td>
</tr>
</tbody>
</table>

In the above output, the (1, 3) cell is empty because the observation for `sex = 0` and `response = 2` has a missing value for `pop`. The (2, 3) cell is empty because there is no observation for `sex = 1` and `response = 2`.

If you specify the `missing` option, rather than cells being left blank, the missing value will be displayed:

```
. tabdisp sex response, cell(pop) missing
```

<table>
<thead>
<tr>
<th>Sex</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12 20 .a</td>
</tr>
<tr>
<td>1</td>
<td>15 11 .</td>
</tr>
</tbody>
</table>

Missing values of the row, column, superrow, and supercolumn variables are allowed, and, by default, missing values are given no special meaning. The output below is from a different dataset.
. use http://www.stata-press.com/data/r15/tabdxmpl5
. list

<table>
<thead>
<tr>
<th>sex</th>
<th>response</th>
<th>pop</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>11</td>
</tr>
<tr>
<td>0</td>
<td>.</td>
<td>26</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>20</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>24</td>
</tr>
<tr>
<td>1</td>
<td>.</td>
<td>44</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
<td>70</td>
</tr>
<tr>
<td>.</td>
<td>0</td>
<td>35</td>
</tr>
<tr>
<td>.</td>
<td>1</td>
<td>35</td>
</tr>
</tbody>
</table>

. tabdisp sex response, cell(pop)

| sex | response
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 15 11 26</td>
</tr>
<tr>
<td>1</td>
<td>20 24 44</td>
</tr>
<tr>
<td>.</td>
<td>35 35 70</td>
</tr>
</tbody>
</table>

If you specify the total option, however, the system missing values are labeled as reflecting totals:

. tabdisp sex response, cell(pop) total

<table>
<thead>
<tr>
<th>sex</th>
<th>response</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 15 11 26</td>
</tr>
<tr>
<td>1</td>
<td>20 24 44</td>
</tr>
<tr>
<td>Total</td>
<td>35 35 70</td>
</tr>
</tbody>
</table>

tabdisp did not calculate the totals; it merely labeled the results as being totals. The number 70 appears in the lower right because there happens to be an observation in the dataset where both sex and response contain a system missing value and pop = 70.

Here the row and column variables were numeric. If they had been strings, the total option would have given the special interpretation to sex = "" and response = "".

**Title**

<table>
<thead>
<tr>
<th>Description</th>
<th>Syntax</th>
<th>Remarks and examples</th>
<th>Stored results</th>
<th>Also see</th>
</tr>
</thead>
</table>

**timer — Time sections of code by recording and reporting time spent**

**Description**

*timer* starts, stops, and reports up to 100 interval timers. Results are reported in seconds.

*timer clear* resets timers to zero.

*timer on* begins a timing. *timer off* stops a timing. A timing may be turned on and off repeatedly without clearing, which causes the timer to accumulate.

*timer list* lists the timings. If # is not specified, timers that contain zero are not listed.

**Syntax**

*Reset timers to zero*

```
timer clear [#]
```

*Turn a timer on*

```
timer on #
```

*Turn a timer off*

```
timer off #
```

*List the timings*

```
timer list [#]
```

where # is an integer, 1–100.

**Remarks and examples**

*timer* can be used to time sections of code. For instance,

```
program tester
    version ...
    timer clear 1
    forvalues repeat=1(1)100 {
        timer on 1
        mycmd ...
        timer off 1
    }
    timer list 1
end
```

649
Stored results

timer list stores the following in r():

Scalars
\begin{align*}
  r(t1) & \quad \text{value of first timer} \\
  r(nt1) & \quad \# \text{ of times turned on and off} \\
  r(t2) & \quad \text{value of second timer} \\
  r(nt2) & \quad \# \text{ of times turned on and off} \\
  \vdots & \quad \vdots \\
  r(t100) & \quad \text{value of 100th timer} \\
  r(nt100) & \quad \# \text{ of times turned on and off}
\end{align*}

Only values for which $r(nt\#) \neq 0$ are stored.
r() results produced by other commands are not cleared.

[P] \texttt{rmsg} — Return messages
**Description**

tokenize divides \textit{string} into tokens, storing the result in ‘1’, ‘2’, \ldots (the positional local macros). Tokens are determined based on the parsing characters \textit{pchars}, which default to a space if not specified.

**Syntax**

tokenize ['"]string"['"] [ , parse("pchars")]

**Option**

parse("pchars") specifies the parsing characters. If \texttt{parse()} is not specified, parse(" ") is assumed, and \textit{string} is split into words. Note that \textit{pchars} is treated as a sequence of bytes. Any Unicode character in multibyte UTF-8 encoding, which applies to all Unicode characters except ASCII characters, is treated as a sequence of bytes rather than as a single character. For example, \texttt{parse()} will not work as expected when trying to break a string into tokens based on a Unicode whitespace character \textbackslash u00a0.

**Remarks and examples**

tokenize may be used as an alternative or supplement to the \texttt{syntax} command (see \texttt{[P] syntax}) for parsing command-line arguments. Generally, it is used to further process the local macros created by \texttt{syntax}, as shown below.

```plaintext
program myprog
    version 15.0
    syntax [varlist] [if] [in]
    marksample touse
    tokenize 'varlist'
    local first '1'
    macro shift
    local rest '*'
    ...
end
```

\textbf{Example 1}

We interactively apply \texttt{tokenize} and then display several of the numbered macros to illustrate how the command works.

```
. tokenize some words
. display "1=|'1'|, 2=|'2'|, 3=|'3'|"
  1=|some|, 2=|words|, 3=||
. tokenize "some more words"
. display "1=|'1'|, 2=|'2'|, 3=|'3'|, 4=|'4'|"
  1=|some|, 2=|more|, 3=|words|, 4=||
```

651
. tokenize ""Marcello Pagano""""Rino Bellocco""",
. display "1="']1', 2="']2', 3="']3''"
1=|Marcello Pagano|, 2=|Rino Bellocco|, 3=||
. local str "A strange++string"
. tokenize 'str'
. display "1="']1', 2="']2', 3="']3''"
1=|A|, 2=|strange++string|, 3=||
. tokenize 'str', parse(" +")
. display "1="']1', 2="']2', 3="']3', 4="']4', 5="']5', 6="']6''"
1=|A|, 2=|strange|, 3=|+|, 4=|+|, 5=|string|, 6=||
. tokenize 'str', parse("+")
. display "1="']1', 2="']2', 3="']3', 4="']4', 5="']5', 6="']6''"
1=|A strange|, 2=|+|, 3=|+|, 4=|string|, 5=||, 6=||
. tokenize
. display "1="']1', 2="']2', 3="']3''"
1=||, 2=||, 3=||

These examples illustrate that the quotes surrounding the string are optional; the space parsing character is not saved in the numbered macros; nonspace parsing characters are saved in the numbered macros together with the tokens being parsed; and more than one parsing character may be specified. Also, when called with no string argument, tokenize resets the local numbered macros to empty.

[M-5] tokens( ) — Obtain tokens from string

[U] 18 Programming Stata
**Description**

`set trace on` traces the execution of programs for debugging. *set trace off* turns off tracing after it has been set on.

`set tracedepth` specifies how many levels to descend in tracing nested programs. The default is 32000, which is equivalent to \( \infty \).

`set traceexpand` indicates whether the lines before and after macro expansion are to be shown. The default is on.

`set tracesep` indicates whether to display a horizontal separator line that displays the name of the subroutine whenever a subroutine is entered or exited. The default is on.

`set traceindent` indicates whether displayed lines of code should be indented according to the nesting level. The default is on.

`set tracenumber` indicates whether the nesting level should be displayed at the beginning of the line. Lines in the main program are preceded with 01; lines in subroutines called by the main program, with 02; etc. The default is off.

`set tracehilite` causes the specified *pattern* to be highlighted in the trace output.

**Syntax**

*Whether to trace execution of programs*

`set trace {on|off}`

*Show # levels in tracing nested programs*

`set tracedepth #`

*Whether to show the lines after macro expansion*

`set traceexpand {on|off} [, permanently]`

*Whether to display horizontal separator lines*

`set tracesep {on|off} [, permanently]`

*Whether to indent lines according to nesting level*

`set traceindent {on|off} [, permanently]`
Whether to display nesting level

set tracenumber \{on|off\} \[, permanently\]

Highlight pattern in trace output

set tracehilit "pattern" \[, word\]

Options

permanently specifies that, in addition to making the change right now, the traceexpand, tracesep, traceindent, and tracenumber settings be remembered and become the default settings when you invoke Stata.

word highlights only tokens that are delimited by nonalphanumeric characters. These would include tokens at the beginning or end of each line that are delimited by nonalphanumeric characters.

Remarks and examples

The set trace commands are extremely useful for debugging your programs.

Example 1

Stata does not normally display the lines of your program as it executes them. With set trace on, however, it does:

```stata
. program list simple
simple:
  1. args msg
  2. if "'msg'"=="hello" {
      3. display "you said hello"
      4. }
  5. else display "you did not say hello"
  6. display "good-bye"
. set trace on
. simple
```

```
----------------------------- begin simple -----------------------------
- args msg
- if "'msg'"=="hello" {
  = if ""=="hello" {
      display "you said hello"
  }
- else display "you did not say hello"
  you did not say hello
- display "good-bye"
  good-bye
----------------------------- end simple -----------------------------
```

Lines that are executed are preceded by a dash. The line is shown before macro expansion, just as it was coded. If the line has any macros, it is shown again, this time preceded by an equal sign and with the macro expanded, showing the line exactly as Stata sees it.

In our simple example, Stata substituted nothing for ‘msg’, as we can see by looking at the macro-expanded line. Because nothing is not equal to “hello”, Stata skipped the display of “you said hello”, so a dash did not precede this line.
To suppress the printing of the macro-expanded lines, type `set traceexpand off`.

To suppress the printing of the trace separator lines, type `set tracesep off`.

The output from our program is interspersed with the lines that caused the output. This can be greatly useful when our program has an error. For instance, we have written a more useful program called `myprog`. Here is what happens when we run it:

```
. myprog mpg, prefix("new")
invalid syntax
r(198);
```

We did not expect this, and, look as we will at our program code, we cannot spot the error. Our program contains many lines of code, however, so we have no idea even where to look. By setting `trace` on, we can quickly find the error:

```
```

The error was close to the top—we omitted the closing quote in the definition of the local `newname` macro.

---

**Technical note**

If you are looking for a command similar to `set trace` for use in Mata, see `mata set matalnum` in [M-3] *mata set*.

---

**Example 2**

`set tracedepth`, `set tracesep`, `set traceindent`, and `set tracenumber` are useful when debugging nested programs. Imagine that we have a program called `myprog1`, which calls `myprog2`, which then calls a modified version of our `simple` program from example 1.

With the default settings, we get:

```
. program list _all

simple2:
1. args msg
2. if ""msg""=""hello" {
3.   display "you said hello"
4. }
```

---
myprog2:
1. args msg
2. simple2 "msg"
3. display "good"

myprog1:
1. args msg
2. myprog2 "msg"
3. display "bye"

.set trace on
.myprog1 hello

- args msg
- myprog2 "msg"
  = myprog2 "hello"

- args msg
- simple2 "msg"
  = simple2 "hello"

- args msg
- if "msg"=="hello" {
  = if "hello"=="hello" {
- display "you said hello"
you said hello
  } 
- else {
  display "you did not say hello"
}

- display "good"
good

- display "bye"
bye

.set trace off

To see the nesting level for each line, you could use set tracenumber on.
. set tracenumber off
. set trace off

If you are interested only in seeing a trace of the first two nesting levels, you could set tracedepth 2.

. set trace on
. set tracedepth 2
. myprog1 hello
     begin myprog1
         - args msg
         - myprog2 """msg""
         = myprog2 """hello""
             begin myprog2
                 - args msg
                 - simple2 """msg""
                 = simple2 """hello""
                 you said hello
                 - display "good"
                 good
             end myprog2
             - display "bye"
             bye
         end myprog2
     end myprog1

By setting tracedepth to 2, the trace of simple2 is not shown.

Finally, if you did not want each nested level to be indented in the trace output, you could set traceindent off.

. set trace on
. set traceindent off
. myprog1 hello
     begin myprog1
         - args msg
         - myprog2 """msg""
         = myprog2 """hello""
             begin myprog2
                 - args msg
                 - simple2 """msg""
                 = simple2 """hello""
             begin simple2
                 - args msg
                 - if """msg""==""""hello"" {
                 = if """"hello""==""""hello"" {
                 - display "you said hello"
                 you said hello
                 - }
                 - else {
                 end simple2
             end myprog2
         end myprog2
     end myprog1
Grace Murray Hopper (1906–1992) was a mathematician, computer scientist, and programmer. She was born in New York City and received a BA in mathematics and physics from Vassar College. Hopper went on to teach at Vassar while earning an MA and a PhD in mathematics from Yale. She joined the Navy during World War II and remained in the Naval Reserve during a long career in academia and private industry. In 1967, she was recalled to active duty to direct the Navy’s Programming Languages Group.

Hopper is best known for developing the first compiler. She also worked extensively to develop programming languages and effective programming techniques. Known as “Grandma COBOL”, Hopper led a team that developed some of the first compiler-based programming languages during the 1950s, work that would lead to the development of COBOL. Hopper is also credited with coining the term “debugging” after her team removed a moth from the Mark II computer she was testing. The moth is still on display at the U.S. Naval Surface Warfare Center Museum.

Among many honors, Hopper was awarded the first ever “computer sciences man of the year” award in 1969. She was the first person from the United States and the first woman to become a Distinguished Fellow of the British Computer Society. She also received the National Medal of Technology and IEEE Emanuel R. Piore Award. In 1997, the U.S. Navy commissioned the USS Hopper in her honor.

unab — Unabbreviate variable list

## Description

unab expands and unabbreviates a varlist (see [U] 11.4 varname and varlists) of existing variables, placing the results in the local macro *lmacname*. unab is a low-level parsing command. The syntax command is a high-level parsing command that, among other things, also unabbreviates variable lists; see [P] syntax.

The difference between unab and tsunab is that tsunab allows time-series operators in *varlist*; see [U] 11.4.4 Time-series varlists.

The difference between tsunab and fvunab is that fvunab allows factor variables in *varlist*; see [U] 11.4.3 Factor variables.

## Syntax

Expand and unabbreviate standard variable lists

```
unab lmacname : [varlist] [, min(#) max(#) name(string)]
```

Expand and unabbreviate variable lists that may contain time-series operators

```
tsunab lmacname : [varlist] [, min(#) max(#) name(string)]
```

Expand and unabbreviate variable lists that may contain time-series operators or factor variables

```
fvunab lmacname : [varlist] [, min(#) max(#) name(string)]
```

## Options

- `min(#)` specifies the minimum number of variables allowed. The default is `min(1)`.
- `max(#)` specifies the maximum number of variables allowed. The default is `max(120000)`.
- `name(string)` provides a label that is used when printing error messages.

## Remarks and examples

Usually, the syntax command will automatically unabbreviate variable lists; see [P] syntax. In a few cases, unab will be needed to obtain unabbreviated variable lists.

If the user has previously set `varabbrev off`, then variable abbreviations are not allowed. Then typing in a variable abbreviation results in a syntax error. See [R] set.
Example 1

The `separate` command (see [D] `separate`) provides an example of the use of `unab`. Required option `by(byvar | exp)` takes either a variable name or an expression. This is not handled automatically by the `syntax` command.

Here the `syntax` command for `separate` takes the form

```stata
syntax varname [if] [in], BY(string) [ other options]
```

After `syntax` performs the command-line parsing, the local variable `by` contains what the user entered for the option. We now need to determine if it is an existing variable name or an expression. If it is a variable name, we may need to expand it.

```stata
capture confirm var `by'
if _rc == 0 {
    unab by: `by', max(1) name(by())
}
else {
    (parse `by' as an expression)
}
```

Example 2

We interactively demonstrate the `unab` command with the `auto` dataset.

```stata
. use http://www.stata-press.com/data/r15/auto
1978 Automobile Data
. unab x: mpg wei for, name(myopt())
. display "'x'"
mpg weight foreign
. unab x: junk
variable junk not found
r(111);
. unab x: mpg wei, max(1) name(myopt())
myopt(): too many variables specified
  1 variable required
r(103);
. unab x: mpg wei, max(1) name(myopt()) min(0)
myopt(): too many variables specified
  0 or 1 variables required
r(103);
. unab x: mpg wei, min(3) name(myopt())
myopt(): too few variables specified
  3 or more variables required
r(102);
. unab x: mpg wei, min(3) max(10)
myopt(): too few variables specified
  3 - 10 variables required
r(102);
. unab x: mpg wei, min(3) max(10)
mpg weight:
too few variables specified
r(102);
```
Example 3

If we created a time variable and used `tsset` to declare the dataset as a time series, we can also expand time-series variable lists.

```
. generate time = _n
. tsset time
. tsunab mylist : l(1/3).mpg
. display "'mylist'")
L.mpg L2.mpg L3.mpg
. tsunab mylist : l(1/3).(price turn displ)
. di "'mylist'")
L.price L2.price L3.price L.turn L2.turn L3.turn L.displacement L2.displacement
> L3.displacement
```

Example 4

If `set varabbrev off` has been issued, variable abbreviations are not allowed:

```
. unab varn : mp
. display "'varn'")
mpg
. set varabbrev off
. unab varn : mp
variable mp not found
r(111);
. set varabbrev on
. unab varn : mp
. display "'varn'")
mpg
```

Reference

[P] syntax — Parse Stata syntax

[P] varabbrev — Control variable abbreviation

[U] 11 Language syntax

[U] 18 Programming Stata
Description

unabcd verifies that *commandname_or_abbreviation* is a Stata command name or an abbreviation of a Stata command name. *unabcd* makes this determination by looking at both built-in commands and ado-files. If *commandname_or_abbreviation* is a valid command, *unabcd* returns in local `r(cmd)` the unabbreviated name. If it is not a valid command, *unabcd* displays an appropriate error message.

Syntax

```
unabcd commandname_or_abbreviation
```

Remarks and examples

Stata’s built-in commands can be abbreviated. For instance, the user can type `gen` for `generate` or `an` for `anova`. Commands implemented as ado-files cannot be abbreviated.

Given a command name *c*, *unabcd* applies the same lookup rules that Stata applies internally. If it is found, the full command name is returned in `r(cmd)`.

Example 1

```
. unabcmd gen
. return list
  macros:
    r(cmd) : "generate"

. unabcmd kappa // kappa is an ado-file
. return list
  macros:
    r(cmd) : "kappa"

. unabcmd ka
  command ka not found as either built-in or ado-file
  r(111);
```

*unabcd* is included just in case you, as a programmer, want the command name spelled out. There is no reason why you should.

Also see

[P] *findfile* — Find file in path
[R] *which* — Display location and version for an ado-file
**varabbrev** — Control variable abbreviation

### Description

`novarabbrev` temporarily turns off variable abbreviation if it is on. `varabbrev` temporarily turns on variable abbreviation if it is off. Also see `set varabbrev` in `[R] set`.

### Syntax

```
novarabbrev `stata_command'
```

```
varabbrev `stata_command'
```

Typical usage is

```
novarabbrev {
    ...
}
```

### Remarks and examples

#### Example 1

```stata
program ..., /* parse input */ ...
novarabbrev {
    ... /* perform task */ ...
}
    ...
end
```

### Also see

- `[R] set` — Overview of system parameters
### Description

`version` with no arguments shows the current internal version number to which the command interpreter is set. It can be used interactively, in do-files, or in ado-files.

`version #` sets the command interpreter and other features such as random-number generators (RNGs) to version number #. `version #` is used to allow old programs to run correctly under more recent versions of Stata and to ensure that new programs run correctly under future versions of Stata.

`version #`: executes `command` under version # and then resets the version to what it was before the `version #`: ... command was given.

For information about external version control, see [R] which.

### Syntax

**Show version number to which command interpreter is set**

`version`

Interactively or in do-files (but not in ado-files or programs defined by `program`)

**Set command interpreter to version # and set other features such as RNGs to version #**

`version #`

`version #`: `command`

In ado-files or programs (but not interactively or in do-files)

**Set command interpreter to version #, but do not set other features such as RNGs to version #**

`version # [, born(ddMONyyyy)]`

`version # [, born(ddMONyyyy)]: command`

Everywhere (interactively, in do-files, in ado-files, and in programs)

**Set only the other features such as RNGs to version #**

`version #, user`

`version #, user: command`
Options

`born(ddMONyyyy)` is rarely specified and indicates that the Stata executable must be dated `ddMONyyyy` (for example, 13Jul2013) or later. StataCorp and users sometimes write programs in ado-files that require the Stata executable to be of a certain date. The `born()` option allows us or the author of an ado-file to ensure that ado-code that requires a certain updated executable is not run with an older executable.

Generally all that matters is the version number, so you would not use the `born()` option. You use `born()` in the rare case that you are exploiting a feature added to the executable after the initial release of that version of Stata. See `help whatsnew` to browse the features added to the current version of Stata since its original release.

`user` causes `version` to backdate other features of Stata. For instance, the results of Stata’s RNGs change—improve—with each version of Stata. The RNGs are said to be under user-version control rather than version control.

If you type `version #` interactively or in your do-files, Stata not only understands old syntax, it backdates (removes) improvements made after #, such as those to the RNGs. You do not have to specify the `user` option. The modern version of Stata will still produce the same results as it produced in the past.

Programmers: When you type `version #` in your programs and ado-files, Stata does not backdate the other improvements. If, for some reason, you want to force the other improvements to be backdated, specify the `user` option. Option `user` is seldom used except by those (say, developers at StataCorp) needing to test that Stata works properly.

Remarks and examples

`version` ensures that programs written under an older release of Stata will continue to work under newer releases of Stata. If you do not write programs and if you use only the programs distributed by StataCorp, you can ignore `version`. If you do write programs, see [U] 18.11.1 Version for guidelines to follow to ensure compatibility of your programs with future releases of Stata.

Technical note

When Stata is invoked, it sets its internal version number to the current version of Stata, which is 15.0 as of this writing. Typing `version` without arguments shows the current value of the internal version number:

```
. version
version 15.0
```

One way to make old programs work is to set the internal version number interactively to that of a previous release:

```
. version 9.0
. version
version 9.0
```

Now Stata’s default interpretation of a program is the same as it was for Stata 9.0.
You cannot set the version to a number higher than the current version. For instance, because we are using Stata 15.0, we cannot set the version number to 15.7.

```
. version 15.7
this is version 15.0 of Stata; it cannot run version 15.7 programs
(output omitted)
r(9);
```

**Technical note**

We strongly recommend that all ado-files and do-files begin with a `version` command. For programs (ado-files), the `version` command should appear immediately following the `program` command:

```
program myprog
    version 15.0
    (etc.)
end
```

**Technical note**

As of Stata 14, Stata’s RNGs were improved, renamed, and restructured; see [R] `set seed`. The default RNG in modern Stata is the 64-bit Mersenne Twister (mt64). Before Stata 14, the RNG was the 32-bit KISS (kiss32). If user version is 14 or higher, RNG results are based on mt64. If user version is less than 14, RNG results are based on kiss32. This also affects the results of commands that use the RNGs, such as `bootstrap`, `bsample`, and the `mi` suite of commands.

**Technical note**

Version control within a RNG is specified at the time the `set seed` command is given, not at the time the random-number generation function such as `rnormal()` is used. For instance, typing

```
. (assume version is set to be 11.2)
. set seed 123456789
. any_command ...
```

causes `any_command` to use the Stata 11.2 version of `rnormal()` even if `any_command` is an ado-file containing an explicit `version` statement setting the version to less than 11.2. This occurs because the version of `rnormal()` that is used was determined at the time the seed was set, and the seed was set under version 11.2 or later.

This works in both directions. Consider

```
. version 11.1: set seed 123456789
. any_command ...
```

In this case, `any_command` uses the older version of `rnormal()` because the seed was set under version 11.1, before `rnormal()` was updated. `any_command` uses the older version of `rnormal()` even if `any_command` itself includes an explicit `version` statement setting the version to 11.2 or later.
Thus both older and newer ado-files can use the newer or older `rnormal()`, and they can do so without modification. The only case in which you need to modify a do-file or ado-file is when it is older, it contains `set seed`, and you now want it to use the new `rnormal()`. In that case, find the `set seed` command in the do-file or ado-file,

```plaintext
version 10 // for example
... set seed 123456789 ...
```

and change it to read

```plaintext
version 10 // for example
... version 11.2: set seed 123456789 ...
```

You need to change only the one line.

Everything written above about prefixing `set seed` with a `version` is irrelevant if you are restoring the seed to a state previously obtained from `c(seed)`:  

```plaintext
set rngstate X075bcd151f123bb5159a55e50022865700023e53
```

The string state `X075bcd151f123bb5159a55e50022865700023e53` includes the version number at the time the seed was set. Prefixing the above with `version`, whether older or newer, will do no harm but is unnecessary.

For an up-to-date summary of version changes, see `help version`.

**Also see**

[P] display — Display strings and values of scalar expressions  
[R] which — Display location and version for an ado-file  
[U] 18.11.1 Version
viewsource — View source code

Description

viewsource searches for filename along the ado-path and displays the file in the Viewer. No default file extension is provided; if you want to see, for example, kappa.ado, type viewsource kappa.ado.

Syntax

viewsource filename

Remarks and examples

Say that you wish to look at the source for ml (documented in [R] ml). You know that ml is an ado-file, and therefore the filename is ml.ado. You type

    . viewsource ml.ado

program (documented in [P] program) is not implemented as an ado-file:

    . viewsource program.ado
    file "program.ado" not found
    r(601);

By the way, you can find out where the file is stored by typing

    . findfile ml.ado
    C:\Program Files\Stata15\ado\base\m\ml.ado

See [P] findfile.

viewsource is not limited to displaying ado-files. If you wish to see, for example, panelsetup.mata, type

    . viewsource panelsetup.mata

Also see

[P] findfile — Find file in path
[R] view — View files and logs
[R] which — Display location and version for an ado-file
while evaluates \( \text{exp} \) and, if it is true (nonzero), executes the \textit{stata\_commands} enclosed in the braces. It then repeats the process until \( \text{exp} \) evaluates to false (zero). \textit{whiles} may be nested within \textit{while}s. If the \( \text{exp} \) refers to any variables, their values in the first observation are used unless explicit subscripts are specified; see [U] 13.7 Explicit subscripting.

Also see [P] foreach and [P] forvalues for alternatives to \texttt{while}.

**Syntax**

\[ \texttt{while \exp \{ \textit{stata\_commands} \}} \]

Braces must be specified with \texttt{while}, and

1. the open brace must appear on the same line as \texttt{while};
2. nothing may follow the open brace, except, of course, comments; the first command to be executed must appear on a new line;
3. the close brace must appear on a line by itself.

**Remarks and examples**

\texttt{while} may be used interactively, but it is most often used in programs. See [U] 18 Programming Stata for a description of programs.

The \texttt{stata\_commands} enclosed in the braces may be executed once, many times, or not at all. For instance,

\begin{verbatim}
program demo
    local i = 'i'
    while 'i'>0 {
        display "i is now 'i'"
        local i = 'i' - 1
    }
    display "done"
end
demo 2
i is now 2
i is now 1
done
demo 0
done
\end{verbatim}
The above example is a bit contrived in that the best way to count down to one would be:

```
program demo
    forvalues i = `1'(-1)1 {
        display "i is now `i"
    }
    display "done"
end
```

`while` is used mostly in parsing contexts:

```
program ...
    ...
    gettoken tok 0 : 0
    while "tok" != "" {
        ...
        gettoken tok 0 : 0
    }
    ...
end
```

or in mathematical contexts where we are iterating:

```
program ...
    ...
    scalar `curval' = .
    scalar `lastval' = .
    while abs(`lastval' - `curval') > `epsilon' {
        scalar `lastval' = `curval'
        scalar `curval' = ...
    }
    ...
end
```

or in any context in which loop termination is based on calculation (whether it be numeric or string).

You can also create endless loops by using `while`,

```
program ...
    ...
    while 1 {
        ...
    }
end
```

which is not really an endless loop if the code reads:

```
program ...
    ...
    while 1 {
        if (...) exit
        ...
    }
    // this line is never reached
end
```

Should you make a mistake and really create an endless loop, you can stop program execution by pressing the *Break* key.
Also see

[P] continue — Break out of loops
[P] foreach — Loop over items
[P] forvalues — Loop over consecutive values
[P] if — if programming command
[U] 13 Functions and expressions
[U] 18 Programming Stata
Description

The `window` command lets you open, close, and manage the windows in Stata’s interface. Using the subcommands of `window menu`, you can also add and delete menu items from the `User` menu from Stata’s main menu bar. `window push` adds `command_line` to the Review window.

For documentation on creating dialog boxes, see [P] `dialog programming`.

Syntax

```
window fopen ...          Display open dialog box
window fsave ...          Display save dialog box
window manage subcmd ...  Manage window characteristics
window menu subcmd ...    Create menus
window push command_line  Copy command into Review window
window stopbox subcmd ...  Display message box
```

[P] `dialog programming` — Dialog programming

[U] 18 Programming Stata
Title

`window fopen` — Display open/save dialog box

Description

`window fopen` and `window fsave` allow Stata programmers to use standard `File > Open...` and `File > Save` dialog boxes in their programs.

Syntax

```
window { fopen | fsave } macroname "title" "filter" [ extension ]
```

Remarks and examples

`window fopen` and `window fsave` call forth the operating system’s standard `File > Open...` and `File > Save` dialog boxes. The commands do not themselves open or save any files; they merely obtain from the user the name of the file to be opened or saved and return it to you. The filename returned is guaranteed to be valid and includes the full path.

The filename is returned in the global macro `macroname`. In addition, if `macroname` is defined at the outset, its contents will be used to fill in the default filename selection.

`title` is displayed as the title of the dialog.

`filter` must be specified. One possible specification is "", meaning no filter. Alternatively, `filter` consists of pairs of descriptions and wildcard file selection strings separated by `|`, such as

"Stata Graphs|*.gph|All Files|*.*"

Stata uses the filter to restrict the files the user sees. The above example allows the user either to see Stata graph files or to see all files. The dialog will display a drop-down list from which the user can select a file type (extension). The first item of each pair (Stata Graphs and All Files) will be listed as the choices in the drop-down list. The second item of each pair restricts the files displayed in the dialog box to those that match the wildcard description. For instance, if the user selects Stata Graphs from the list box, only files with extension `.gph` will be displayed in the file dialog box.

Finally, `extension` is optional. It may contain a string of characters to be added to the end of filenames by default. For example, if the `extension` were specified as `xyz`, and the user typed a filename of `abc` in the file dialog box, `abc.xyz` would be returned in `macroname`.

In Windows, the default `extension` is ignored if a `filter` other than `*.*` is in effect. For example, if the user’s current filter is `*.gph`, the default extension will be `.gph`, regardless of the `extension` specified.

Because Windows allows long filenames, `extension` can lead to unexpected results. For example, if `extension` were specified as `xyz` and the user typed a filename of `abc.def`, Windows would append `.xyz` before returning the filename to Stata, so the resulting filename is `abc.def.xyz`. Windows users should be aware that if they want to specify an extension different from the default, they must enter a filename in the file dialog box enclosed in double quotes: "abc.def". This applies to all programs, not just Stata.
If the user presses the Cancel button on the file dialog, `window fopen` and `window fsave` set *macroname* to be empty and exit with a return code of 601. Programmers should use the `capture` command (see [P] capture) to prevent the 601 return code from appearing to the user.

```
begin dtaview.ado
  program dtaview
    version 15.0
    capture window fopen D_dta "Select a dataset to use:" /*
      */ "Stata Data (*.dta)|*.dta|All Files (*.*)|*.*" dta
    if _rc==0 {
      display "User chose $D_dta as the filename."
      use "$D_dta"
    }
  end
end dtaview.ado
```

[P] window programming — Programming menus and windows

[P] window stopbox — Display message box
window manage — Manage window characteristics

Description

window manage allows Stata programs to invoke features from Stata’s main menu.

Syntax

Minimize or restore the main Stata window

    window manage minimize
    window manage restore

Manage window preferences

    window manage prefs { load "prefname" | save "prefname" | default }

Restore file associations (Windows only)

    window manage associate

Reset main window title (Unix and Windows only)

    window manage maintitle { reset | "title" }

Set Dock icon’s label (Mac only)

    window manage docklabel [ "label" ]

Bring windows forward

    window manage forward window-name

where window-name can be command, doeditor, graph, help, results, review, variables, or viewer.
Commands to manage Graph windows

`window manage print graph`

`window manage forward graph ["graphname"]`

`window manage close graph [{"graphname" | _all}]`

`window manage rename graph oldgraphname newgraphname`

Commands to manage Viewer windows

`window manage print viewer ["viewernname"]`

`window manage forward viewer ["viewernname"]`

`window manage close viewer [{"viewernname" | _all}]`

Remarks and examples

`window manage` accesses various parts of Stata’s windowed interface that would otherwise be available only interactively. For instance, say that a programmer wanted to ensure that the Graph window was brought to the front. An interactive user would do that by selecting `Graph` from the `Window` menu. A Stata program could be made to do the same thing by coding `window manage forward graph`.

Remarks are presented under the following headings:

- Minimizing or restoring the main window
- Windowing preferences
- Restoring file associations (Windows only)
- Resetting the main window title
- Setting Dock icon’s label (Mac only)
- Bringing windows forward
- Commands to manage Graph windows
- Commands to manage Viewer windows

Minimizing or restoring the main window

`window manage minimize` minimizes (hides) the Stata window. With Stata for Windows and Stata for Unix, this has the same effect as clicking on the minimize button on Stata’s title bar. With Stata for Mac, this has the same effect as selecting `Hide Stata` from the `Stata` menu.
For example,

```
window manage minimize
```

minimizes the overall Stata window if you are using Stata for Windows or Stata for Unix and hides Stata’s windows if you are using Stata for Mac.

```
window manage restore
```

restores the Stata window if necessary.

With Stata for Windows, this command has the same effect as clicking the Stata button on the taskbar. With Stata for Mac, this command has the same effect as clicking on the Stata icon on the Dock. With Stata for Unix, this command has the same effect as clicking on the Stata icon in the Window Manager.

For example,

```
window manage restore
```

restores Stata’s overall window to its normal, nonminimized state.

**Windowing preferences**

```
window manage prefs { load "prefname" | save "prefname" | default }
```

loads, saves, and restores windowing preferences.

```
window manage prefs load "prefname" is equivalent to selecting Edit > Preferences > Load preference set and loading a named preference set. window manage prefs save "prefname" is equivalent to selecting Edit > Preferences > Save preference set and naming a new preference set. window manage prefs default is equivalent to selecting Edit > Preferences > Load preference set > Widescreen layout (default). In Stata for Mac, the Preferences menu is located in the Stata menu.
```

For example,

```
window manage prefs default
```

restores Stata’s windows to their “factory” appearance.

**Restoring file associations (Windows only)**

In Stata for Windows, `window manage associate` restores the default actions for Stata file types. For example, another application could take over the `.dta` extension so that double-clicking on a Stata dataset would no longer launch Stata. `window manage associate` restores the association between all Stata file extensions (such as `.dta`) and Stata. This is equivalent to selecting Edit > Preferences > Reset file associations.

**Resetting the main window title**

In Stata for Unix and Stata for Windows, `window manage maintitle "title"` changes the title of the main Stata Window. The title may be reset to the default with `window manage maintitle reset`. 
Setting Dock icon's label (Mac only)

In Stata for Mac, `window manage docklabel "label"` sets the label to be displayed in the badge area of Stata's application icon in the Dock. To clear the badge label, enter the command with no label. You should limit the label to 6 characters or fewer; otherwise, the label will be truncated.

`window manage docklabel` can be useful for displaying the progress of a do-file.

For example,

```plaintext
begin test.do
  do test1.do
    window manage docklabel "25%"
  do test2.do
  window manage docklabel "50%"
  do test3.do
  window manage docklabel "75%"
  do test4.do
end test.do
```

Bringing windows forward

`window manage forward window-name` brings the specified window to the top of all other Stata windows. This command is equivalent to selecting one of the available windows from the Window menu. The following table lists the `window-names` that `window manage forward` understands:

<table>
<thead>
<tr>
<th><code>window-name</code></th>
<th>Stata window</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>Command window</td>
</tr>
<tr>
<td>doeditor</td>
<td>Do-file editor window</td>
</tr>
<tr>
<td>graph</td>
<td>Graph window</td>
</tr>
<tr>
<td>help</td>
<td>Help/search window</td>
</tr>
<tr>
<td>results</td>
<td>Results window</td>
</tr>
<tr>
<td>review</td>
<td>Review window</td>
</tr>
<tr>
<td>variables</td>
<td>Variables window</td>
</tr>
<tr>
<td>viewer</td>
<td>Viewer window</td>
</tr>
</tbody>
</table>

If a window had not been available on Stata's Window menu (if it had been grayed out), specifying `window-name` after `window manage forward` would do nothing. For example, if there is no current graph, `window manage forward graph` will do nothing; it is not an error.

For example,

```plaintext
window manage forward results
```

brings the Results window to the top of the other Stata windows.

Under Stata for Mac and Stata for Unix, specifying the Command, Results, Review, or Variables windows will bring the main Stata window forward because these windows are all contained within one window.
Commands to manage Graph windows

Printing

window manage print graph invokes the action of the File > Print > Graph (Graph) menu item. If there is no current graph, window manage print does nothing; it does not return an error.

For example,

    window manage print graph

displays the print dialog box just as if you pulled down File > Print > Graph (Graph).

Bringing forward

window manage forward graph [graphname] brings the Graph window named graphname, if it exists, to the top of other windows. If graphname is not specified and there are multiple graph windows open, window manage forward graph brings the topmost Graph window to the top of other windows.

Closing

window manage close graph [graphname | _all] closes the Graph windows named graphname, if it exists. If _all is specified, all Graph windows are closed. If graphname is not specified and an unnamed Graph window exists, the unnamed Graph window will be closed. Note that this command is not intended for end users; it is a utility to be used by graph close. End users should use graph close.

Renaming

window manage rename graph oldgraphname newgraphname renames the Graph window named oldgraphname, if it exists, to newgraphname. Note that this command is not intended for end users; it is a utility to be used by graph rename. End users should use graph rename.

Commands to manage Viewer windows

Printing

window manage print viewer [viewername] prints the Viewer window named viewername, if it exists. If viewername is not specified and there are multiple Viewer windows open, window manage prints the topmost Viewer window. If there is no current Viewer window, window manage print does nothing; it does not return an error.

Bringing forward

window manage forward viewer [viewername] brings the Viewer window named viewername, if it exists, to the top of other windows. If viewername is not specified and there are multiple Viewer windows open, window manage brings the topmost Viewer window to the top of other windows.

Closing

window manage close viewer [viewername | _all] closes the Viewer window named viewername, if it exists. If _all is specified, all Viewer windows are closed. If viewername is not specified and an unnamed Viewer window exists, the unnamed Viewer window will be closed.

[P] window programming — Programming menus and windows
Description

`window menu` allows you to add new menu hierarchies.

Syntax

Clear previously defined menu additions

```
window menu clear
```

Define submenus

```
window menu append submenu "defined_menuuname" "appending_menuuname"
```

Define menu item

```
window menu append item "defined_menuuname" "entry_text" "command_to_execute"
```

Define separator bars

```
window menu append separator "defined_menuuname"
```

Activate menu changes

```
window menu refresh
```

Add files to the Open recent menu

```
window menu add_recentfiles "filename" [, rlevel(#)]
```

The quotation marks above are required.

"defined_menuuname" is the name of a previously defined menu or one of the user-accessible menus "stUser", "stUserData", "stUserGraphics", or "stUserStatistics".
Remarks and examples

Remarks are presented under the following headings:

- Overview
- Clear previously defined menu additions
- Define submenus
- Define menu items
- Define separator bars
- Activate menu changes
- Add files to the Open recent menu
- Keyboard shortcuts (Windows only)
- Examples
- Advanced features: Dialogs and built-in actions
- Advanced features: Creating checked menu items
- Putting it all together

Overview

A menu is a list of choices. Each choice may be another menu (known as a submenu) or an item. When you click on an item, something happens, such as a dialog box appearing or a command being executed. Menus may also contain separators, which are horizontal bars that help divide the menu into groups of related choices.

Stata provides the top-level menus Data, Graphics, Statistics, and User to which you may attach your own submenus, items, or separators.

A menu hierarchy is the collection of menus and how they relate.

window menu allows you to create menu hierarchies, set the text that appears in each menu, set the actions associated with each menu item, and add separators to menus.

New menu hierarchies are defined from the top down, not from the bottom up. Here is how you create a new menu hierarchy:

1. You append to some existing Stata menu a new submenu using window menu append submenu. That the new submenu is empty is of no consequence.
2. You append to the new submenu other submenus, items, or separators, all done with window menu append. In this way, you fill in the new submenu you already appended in step 1.
3. If, in step 2, you appended submenus to the menu you defined in step 1, you append to each of them so that they are fully defined. This requires even more window menu append commands.
4. You keep going like this until the full hierarchy is defined. Then you tell Stata’s menu manager that you are done using window menu refresh.

Everything you do up to step 4 is merely definitional. At step 4, what you have done takes effect.

You can add menus to Stata. Then you can add more menus. Later, you can add even more menus. What you cannot do, however, is ever delete a little bit of what you have added. You can add some menus and window menu refresh, then add some more and window menu refresh, but you cannot go back and remove part of what you added earlier. What you can do is remove all the menus you have added, restoring Stata to its original configuration. window menu clear does this.
So, in our opening example, how did the **Regression** submenu ever get defined? By typing

```plaintext
  . window menu append submenu "stUserStatistics" "Regression"
  . window menu append item "Regression" "Simple" ...
  . window menu append item "Regression" "Multiple" ...
  . window menu append item "Regression" "Multivariate" ...
  . window menu refresh
```

*stUserStatistics* is the special name for Stata's **User–Statistics** built-in menu. The first command appended a submenu to *stUserStatistics* named **Regression**. At this point, **Regression** is an empty submenu.

The next three commands filled in **Regression** by appending to it. All three are items, meaning that when chosen, they invoke some Stata command or program. (We have not shown you what the Stata commands are; we just put “…” to indicate them.)

Finally, *window menu refresh* told Stata we were done and to make our new additions available.

### Clear previously defined menu additions

```plaintext
  window menu clear
```

clears any additions that have been made to Stata's menu system.

### Define submenus

```plaintext
  window menu append submenu "defined_menu_name" "appending_menu_name"
```

defines a submenu. This command creates a submenu with the text *appending_menu_name* (the double-quote characters do not appear in the submenu when displayed) attached to the *defined_menu_name*. It also declares that the *appending_menu_name* can later have further submenus, items, and separators appended to it. Submenus may be appended to Stata's built-in **User** menu using the command

```plaintext
  window menu append submenu "stUser" "appending_menu_name"
```

For example,

```plaintext
  window menu append submenu "stUser" "New Menu"
```

appends **New Menu** to Stata's **User** menu. Likewise, submenus may be appended to the built-in submenus of **User**—**Data**, **Graphics**, and **Statistics**—by using *stUserData*, *stUserGraphics*, or *stUserStatistics* as the *defined_menu_name*.

### Define menu items

```plaintext
  window menu append item "defined_menu_name" "entry_text" "command_to_execute"
```

defines menu items. This command creates a menu item with the text *entry_text*, which is attached to the *defined_menu_name*. When the item is selected by the user, *command_to_execute* is invoked.

For example,

```plaintext
  window menu append item "New Menu" "Describe" "describe"
```

appends the menu item **Describe** to the **New Menu** submenu defined previously and specifies that if the user selects **Describe**, the *describe* command is to be executed.
Define separator bars

```
window menu append separator "defined_menuName"
```

defines a separator bar. The separator bar will appear in the position in which it is declared and is attached to an existing submenu.

For example,

```
window menu append separator "New Menu"
```

adds a separator bar to `New Menu`.

Activate menu changes

```
window menu refresh
```

activates the changes made to Stata’s menu system.

Add files to the Open recent menu

The `Open recent` menu is a list of datasets recently used or saved by the user. Selecting a dataset from the menu causes Stata to execute a `use` command on the dataset to load the data. The datasets are represented in the list as the absolute path or URL to the dataset.

A dataset is added to the list if the dataset is loaded by the command `use` or saved by the command `save`. The list is ordered from the most recently used datasets to the least recently used datasets. The maximum number of datasets in the list is twenty and datasets are removed from the bottom of the list when the maximum is reached. If a dataset already exists in the list when it is to be added, the existing entry is moved to the top of the list.

The list of datasets from the `Open recent` menu is saved when exiting Stata and loaded when starting Stata. Stata removes datasets that do not exist from the list when it exits and starts but not during a session. Stata does not attempt to determine if a URL is valid.

```
window menu add_recentfiles "filename" [, rlevel(#)]
```

adds a dataset to the `Open recent` menu under the `File` menu. Only datasets should be added to the `Open recent` menu.

To prevent temporary files from being added to the `Open recent` menu, Stata does not add datasets used or saved by do-files and ado-files or when running a batch file. However, for the cases where you do wish to add a dataset used or saved by an ado-file or do-file, you may use the `rlevel()` option.

The `rlevel()` option determines the maximum run level an ado-file issuing the `window menu add_recentfiles` may run at for a dataset to be added to the `Open recent` menu. If no ado-file is running, the run level is 0. If an ado-file executes another ado-file which executes another ado-file before returning to the previous ado-file, the run level is 3. `rlevel(0)` adds a dataset only if no ado-file or do-file is running and is the default. `rlevel(3)` adds a dataset if an ado-file is up to 3 levels deep when called. `rlevel(-1)` adds a dataset regardless of the run level and is the only way to add a dataset from a do-file.

For example, `sysuse` is implemented as an ado-file. We want to add datasets loaded by `sysuse` to the `Open recent` menu only if the user entered `sysuse` from the command line. We add to `sysuse.ado`

```
window menu add_recentfiles "filename", rlevel(1)
```
If we had used a run level of 2, any dataset loaded by *sysuse* from an ado-file would be added to the **Open recent** menu which is not what we want.

**Keyboard shortcuts (Windows only)**

When you define a menu item, you may assign a keyboard shortcut. A shortcut (or keyboard accelerator) is a key that allows a menu item to be selected via the keyboard in addition to the usual point-and-click method.

By placing an ampersand (&) immediately preceding a character, you define that character to be the shortcut. The ampersand will not appear in the menu item, but the character following the ampersand will be underlined to alert the user of the shortcut. The user may then choose the menu item by either clicking with the mouse or holding down *Alt* and pressing the shortcut key. Actually, you only have to hold down *Alt* for the top-level menu. For the submenus, once they are pulled down, holding down *Alt* is optional.

If you need to include an ampersand as part of the "entry_text", place two ampersands in a row.

It is your responsibility to avoid creating conflicting keyboard shortcuts. When the user types in a keyboard shortcut, Stata finds the first item with the defined shortcut.

Example:

```
window menu append submenu "stUserStatistics" "&Regression"
```

defines a new submenu named **Regression** that will appear in the **User–Statistics** menu and that users may access by pressing *Alt*-*U* (to open the **User** menu), then *S* (to open the **Statistics** menu), and finally *R*, the shortcut defined for **Regression**.

**Examples**

Below we use the *window menu* commands to add to Stata’s existing top-level menu. The following may be typed interactively:

```
window menu clear
window menu append submenu "stUser" "&My Data"
window menu append item "My Data" "&Describe data" "describe"
window menu refresh
```

**window menu clear**

Clears any user-defined menu items and restores the menu system to the default.

```
window menu append submenu "stUser" "&My Data"
```

**Appends to the **User** a new submenu called **My Data**. Note that you may name this new menu anything you like. You can capitalize its name or not. You may include spaces in it. The new menu appears as the last item on the **User** menu.

```
window menu append item "My Data" "&Describe data" "describe"
```

**Defines a menu item (including a keyboard shortcut) named **Describe data** to appear within the **My Data** submenu. This name is what the user will actually see. It also specifies the command to execute when the user selects the menu item. In this case, we will run the **describe** command.

**window menu refresh**

**Causes all the menu items that have been defined and appended to the default system menus to become active and to be displayed.**
Advanced features: Dialogs and built-in actions

Recall that menu items can have associated actions:

```
window menu append item "defined_menuitem" "entry_text" "command_to_execute"
```

Actions other than Stata commands and programs can be added to menus. In the course of designing a menu system, you may include menu items that will invoke dialogs, open a Stata dataset, save a Stata graph, or perform some other common Stata menu command.

You can specify "command_to_execute" as one of the following:

"DB dialog_to_invoke"
invokes the dialog box defined by the file `dialog_to_invoke.dlg`. For example, specifying "DB regress" as the "command_to_execute" results in the dialog box for Stata’s `regress` command being invoked when the item is selected.

"XEQ about"
displays Stata’s About dialog box. The About dialog box is accessible from the default system menu by selecting About from the File menu.

"XEQ save"
displays Stata’s Save dialog box to save the dataset in memory. This dialog box is accessed from the default system menu by selecting Save from the File menu.

"XEQ saveas"
displays Stata’s Save Data As dialog box to save the dataset in memory. This dialog box is accessible from the default system menu by selecting Save as... from the File menu.

"XEQ savegr"
displays the Save Stata Graph File dialog box, which saves the currently displayed graph. This dialog box is accessible from the default system by selecting Save as... from the File menu of the Graph Editor.

"XEQ printgr"
prints the graph displayed in the Graph window. This is available in the default menu system by selecting Print Graph from the File menu. Also see [P] window manage.

"XEQ use"
displays Stata’s Open dialog box, which loads a Stata dataset. This is available in the default menu system by selecting Open... from the File menu.

"XEQ exit"
exits Stata. This is available from the default menu system by selecting Exit from the File menu (or selecting Quit from the Stata menu on Mac).

"XEQ conhelp"
opens the Stata help system to the default welcome topic. This is available by clicking on the Help! button in the help system.

Advanced features: Creating checked menu items

```
command_to_execute in
window menu append item "defined_menuitem" "entry_text" "command_to_execute"
```
may also be specified as CHECK macroname.
Another detail that menu designers may want is the ability to create checked menu items. A checked menu item is one that appears in the menu system as either checked (includes a small check mark to the right) or not.

"CHECK macroname" specifies that the global macro macroname should contain the value as to whether or not the item is checked. If the global macro is not defined at the time that the menu item is created, Stata defines the macro to contain zero, and the item is not checked. If the user selects the menu item to toggle the status of the item, Stata will place a check mark next to the item on the menu system and redefine the global macro to contain one. In this way, you may write programs that access information that you gather via the menu system.

Note that you should treat the contents of the global macro associated with the checked menu item as “read only”. Changing the contents of the macro will not be reflected in the menu system.

Putting it all together

In the following example, we create a larger menu system. Note that each submenu defined using window menu append submenu contains other submenus and/or items defined with window menu append item that invoke commands.

```stata
begin lgmenu.do

capture program drop mylgmenu
program mylgmenu
    version 15.0
    win m clear
    win m append submenu "stUserStatistics" "&Regression"
    win m append submenu "stUserStatistics" "&Tests"
    win m append item "Regression" "&OLS" "DB regress"
    win m append item "Regression" "Multi&variate" "choose multivariate"
    win m append item "stUserGraphics" "&Scatterplot" "choose scatterplot"
    win m append item "stUserGraphics" "&Histogram" "myprog1"
    win m append item "stUserGraphics" "Scatterplot &Matrix" "choose matrix"
    win m append item "stUserGraphics" "&Pie chart" "choose pie"
    win m append submenu "Tests" "Test of &mean"
    win m append item "Tests" "Test of &variance" "choose variance"
    win m append item "Test of mean" "&Unequal variances" "CHECK DB_uv"
    win m append separator "Test of mean"
    win m append item "Test of mean" "t-test &by variable" "choose by"
    win m append item "Test of mean" "t-test two &variables" "choose 2var"
    win m refresh
end

capture program drop choose
program choose
    version 15.0
    if ":'1'" == "by" | ":'1'" == "2var" {
        display as result ":'1'" as text " from the menu system"
        if $DB_uv {
            display as text " use unequal variances"
        } else {
            display as text " use equal variances"
        }
    } else {
        display as result ":'1'" as text " from the menu system"
    }
end

capture program drop myprog1
```

686  window menu — Create menus
Running this do-file will define a program mylgmenu that we may use to set the menus. Note that, other than the OLS item, which launches the `regress` dialog box, the menu items will not run any interesting commands, as the focus of the example is in the design of the menu interface only. To see the results, type `mylgmenu` in the Command window after you run the do-file. Below is an explanation of the example.

The command

```plaintext
win m append submenu "stUserStatistics" "&Regression"
```

adds a submenu named Regression to the built-in menu Statistics under the User menu. If the user clicks on Regression, we will display another menu with items defined by

```plaintext
win m append item "Regression" "&OLS" "DB regress"
win m append item "Regression" "Multi&variate" "choose multivariate"
```

Because none of these entries open further menus, they use the item version instead of the submenu version of the `window menu append` command.

Similarly, the built-in User–Graphics menu is populated using `window menu item` commands.

```plaintext
win m append item "stUserGraphics" "&Scatterplot" "choose scatterplot"
win m append item "stUserGraphics" "&Histogram" "myprog1"
win m append item "stUserGraphics" "Scatterplot &Matrix" "choose matrix"
win m append item "stUserGraphics" "&Pie chart" "choose pie"
```

For the Tests submenu, we decided to have one of the entries be another submenu for illustration. First, we declared the Tests menu to be a submenu of User–Statistics using

```plaintext
win m append submenu "stUserStatistics" "&Tests"
```

We then defined the entries that were to appear below the Tests menu. There are two entries: one of them is another submenu, and the other is an item. For the submenu, we then defined the entries that are below it.

Finally, note how the commands that are run when the user makes a selection from the menu system are defined. For most cases, we simply call the same program and pass an argument that identifies the menu item that was selected. Each menu item may call a different program if you prefer. Also note how the global macro that was associated with the checked menu item is accessed in the programs that are run. When the item is checked, the global macro will contain 1. Otherwise, it contains zero. Our program merely has to check the contents of the global macro to see if the item is checked or not.

[P] window programming — Programming menus and windows
Description

`window push` copies the specified *command-line* onto the end of the command history. *command-line* will appear as the most recent command in the `#review` list and will appear as the last command in the Review window.

Syntax

```
window push command-line
```

Remarks and examples

`window push` is useful when one Stata command creates another Stata command and executes it. Normally, commands inside ado-files are not added to the command history, but an ado-file such as a dialog interface to a Stata command might exist solely to create and execute another Stata command.

`window push` allows the interface to add the created command to the command history (and therefore to the Review window) after executing the command.

```
begin example.do
  program example
    version 15.0
    display "This display command is not added to the command history"
    display "This display command is added to the command history"
    window push display "This display command is added to the command history"
  end
end example.do
```

This display command is not added to the command history
This display command is added to the command history

```
. example
This display command is not added to the command history
This display command is added to the command history
. #review
3
2 example
1 display "This display command is added to the command history"
```

window stopbox — Display message box

Description

window stopbox allows Stata programs to display message boxes. Up to four lines of text may be displayed on a message box.

Syntax

```
window stopbox { stop | note | rusure } [ "line 1" [ "line 2" [ "line 3" [ "line 4" ] ] ] ]
```

Remarks and examples

There are three types of message boxes available to Stata programmers. The first is the stop message box. `window stopbox stop` displays a message box intended for error messages. This type of message box always exits with a return code of 1.

```stata
. window stopbox stop "You must type a variable name." "Please try again."
(stop message box is displayed)
—Break—
r(1);
```

The second message box is the note box. `window stopbox note` displays a message box intended for information messages or notes. This type of message box always exits with a return code of 0.

```stata
. window stopbox note "You answered 3 of 4 questions correctly."
> "Press OK to continue."
(note message box is displayed)
```

The only way to close the first two types of message boxes is to click the OK button displayed at the bottom of the box.

The third message box is the rusure (say, “Are you sure?”) box. This message box lets a Stata program ask the user a question. The user can close the box by clicking either Yes or No. The message box exits with a return code of 0 if the user clicks Yes, or exits with a return code of 1 if the user clicks No.

A Stata program should use the capture command to determine whether the user clicked Yes or No.

```stata
. capture window stopbox rusure
> "Do you want to clear the current dataset from memory?"
(rusure message box is displayed)
. if _rc == 0 clear
```
